to help restore
nd stabilize the
ntestinal flora
for fever blisters
and canker sores
of herpetic origin

LACTINEX®

TABLETS & GRANULES

LACTINEX—a viable culture containing both *Lactobacillus acidophilus* and *L. bulgaricus*—was first introduced to help restore the flora of the intestinal tract in infants and adults.[1, 2, 3, 4]

Further clinical work showed LACTINEX to be successful in the treatment of fever blisters and canker sores of herpetic origin.[4, 5, 6, 7]

No untoward side effects have been reported in 12 years of clinical use.

Literature on indications and dosage available on request.

Neo-Synephrine is a standard among topical vasoconstrictors. It is unsurpassed for reducing nasal turgescence in colds; and a most valuable aid in preventing and treating sinusitis.

Neo-Synephrine stops the boggy feeling of colds at once—works against factors that induce sinusitis. With Neo-Synephrine nose drops, spray or jelly, turbinates shrink on contact, obstructed ostia open and drainage is re-established.

In sinusitis, Neo-Synephrine helps to promote drainage and hasten recovery.* Used promptly, it helps clear the stagnant sinus and lessen the chances of chronicity.

Neo-Synephrine HCl is available in:
1/8% solution for infants
1/4% solution for children and adults
1/4% pediatric nasal spray for children
1/2% solution for adults
1/2% nasal spray for adults
1/2% jelly for children and adults
1% solution for adults (resistant cases)

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

An antibiotic of choice is one that works

TAO works

Susceptibility Results
Staphylococci [2,3,1]

# OF CULTURES	YEAR	% EFFECTIVE
6,725	1962	88.6%
5,440	1963	88.0%
10,384	1964	88.5%

β-Hemolytic Streptococci [2,3,1]

# OF CULTURES	YEAR	% EFFECTIVE
2,448	1962	89.5%
1,519	1963	95.2%
2,492	1964	96.7%

The Product

In a world study of antibiotics ***in vitro***[1], TAO had an overall effectiveness of 87.3%, higher than chloramphenicol and erythromycin, and significantly higher than tetracycline and penicillin.

The Plus... Consistent Performance

Yet antibiotics must not only work. They must work consistently. Here are the results from the largest study of microbial susceptibility ever undertaken. In 29,048 cultures of overt staphylococcal and β-hemolytic streptococcal infections, note the consistency of results with TAO.

TAO®
[triacetyloleandomycin]

J. B. Roerig and Company, New York, New York 10017
Division, Chas. Pfizer & Co., Inc., Science for the World's Well-Being®

TAO Rx information

Indications: The bacterial spectrum includes: streptococci, staphylococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents. **Contraindications and Precautions:** TAO (triacetyloleandomycin) is not recommended for prophylaxis or in the treatment of infectious processes which may require more than ten days continuous therapy. In view of the possible hepatotoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents, of course, should be used. If clinical judgement dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. It is contraindicated in pre-existing liver disease or dysfunction, and in individuals who have shown hypersensitivity to the drug. Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions. **References:** 1. Isenberg, Henry D.: Health Laboratory Science **2**:163-173 (July) 1965. 2. Fowler, J. Ralph et al: Clinical Medicine **70**:547 (Mar.) 1963. 3. The Pain Is Gone

Despite introduction of synthetic substitutes, efficacy of 'Empirin' Compound with Codeine remains unchallenged.

'Empirin'® Compound with Codeine Phosphate gr. 1/2 No. 3

Each tablet contains: Codeine Phosphate gr. ½ (Warning—May be habit forming), Phenacetin gr. 2½, Aspirin gr. 3½, Caffeine gr. ½.

Keeps the Promise of Pain Relief

BURROUGHS WELLCOME & CO. (U.S.A.) INC., TUCKAHOE, N.Y.

President's Letter

To be elected President of the Minnesota State Medical Association is a great honor, one to be accepted with humility, for the office carries with it many responsibilities. The development of the scientific program for the following year, certain committee appointments, attendance at multiple meetings and functions are part of the President's obligations, but are of less significance than the major responsibility: that of spokesman for the Association.

All of us realize that medicine is at a crossroad, and that the choice of direction is no longer entirely ours. We can, hopefully, indicate in the future what path we prefer, but our choice will depend in large part on the unified resistance we present to misdirection.

Since the President is identified as the spokesman for Association policy and principle, he must be alert to and aware of Association attitudes, in order that he be prepared to explain, and, if necessary, defend these attitudes.

Through county society delegate election, and subsequent House of Delegate reference committee hearings and recommendations to the House, every member has a choice in determining Association policy. The Council in the interim between sessions of the House further clarifies Association policy and the principles on which Association actions are based.

These procedures in the House and in the Council structure are the official method to fully present, and represent the thinking of the physicians of Minnesota.

Occasionally, it is true, individual physician opinion may not coincide with Association action. In areas as controversial as the future response of medicine to governmental regulation, some difference of opinion inevitably occurs. The actions of the Association are, however, always the distillate of elected representative opinion and should be accepted as such.

Varying opinions can, and should, be expressed in component society meetings, before reference committees, before the House of Delegates itself, and by way of the always open door to Council deliberations.

Never in the past has a united front been so necessary to medicine, for never in the past have physician statements been so suspect and so freely criticized.

This is in no sense a plea for conformity, for conformity alone leads to compulsion, and agreement without honest discussion of issues leads to complacency. It is, rather, a plea for individual physician participation in the formation of Association policy through active component society attendance, through delegate instruction, through attendance at the annual meetings, at the House of Delegates, and at the reference committees which shape policy for recommendation to the House.

By this participation, the physicians of Minnesota can clearly express medical policy, motivation and philosophy, individually and as members of a stronger Association.

RP Buckley M.D.

R. P. Buckley, M.D.
President
Minnesota State Medical Association

Low host resistance?

Consider the "extra" antibacterial activity of Ilosone®

Occasionally, therapeutic failure is due to the patient's inability to mobilize his defenses sufficiently to overcome infection. Typical of this is the debilitated patient, the premature infant, or the diabetic. It is in these patients that the high levels of antimicrobial activity of Ilosone are especially useful. Ilosone has demonstrated antibacterial levels two to four times those of erythromycin base or stearate. Furthermore, it attains them earlier and maintains them longer. Even the presence of food does not appear to affect the activity of Ilosone.

Contraindications: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

Side-Effects: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

Dosage: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Ilosone®

Erythromycin Estolate

Aneurysmal Abscess*

HUBERT C. HUEBL, M.D.****
RAYMOND C. READ, M.D., Ph.D., F.A.C.S.****
Detroit, Michigan

ALTHOUGH INFECTION is an unusual cause of aneurysm, we have recently encountered four cases which resulted from arterial injection. Two followed carotid arteriography; the others occurred in addicts who had been introducing concentrated paregoric mixtures into their femoral veins. In each instance the lesion presented as a pulsating abscess and was treated by ligature, incision, and wide drainage.

It is our purpose to document this experience and to describe the relative importance of extravasation, contamination, intramural injection, and chemical necrosis in its etiology. In addition, the question of immediate or delayed vascular reconstruction will be discussed.

Case Reports

Case #1

A 53-year-old negro male was admitted to Detroit Receiving Hospital on January 4, 1964, because of the onset of headache associated with tingling, decreased sensation, and weakness in his left upper and lower extremities. On physical examination his blood pressure was 170/110. He was obtunded† and poorly oriented, but responded to simple commands. Speech was slurred. He was noted to have a left facial paresis and a left hemiparesis and hypesthesia. Deep tendon reflexes were diminished on the left. There was slight nuchal resistance. Initial laboratory studies were within normal limits. Lumbar puncture revealed an opening pressure of 370 mm. of saline and a closing pressure of 300. The fluid was bloody. Protein was 420 mgm%.

Diagnostic Procedure

On the day following admission, bilateral carotid arteriograms were performed using Renografin 60. This revealed marked tortuosity and kinking of the internal carotid arteries and cerebral vessels, especially on the right. No other abnormalities were seen. He was noted to have extravasation of dye into the right carotid sheath, which was controlled with pressure. Bilateral brachial-vertebral arteriograms showed no pathology in the subclavian or vertebral vessels.

He began to improve, but on the seventh day following arteriography he was observed to have a pulsating, tender mass involving the entire right side of his neck from the occiput to the sternum, associated with a Horner's syndrome. The mass was reported to have appeared during the preceding twenty-four hours and was rapidly expanding. His temperature rose to 104° and his pulse increased to 130. A tracheotomy was performed by the Eye, Nose and Throat service because the trachea was shifted to the left and he had pressure symptoms from the mass.

Operative Findings

The right side of the neck was explored. There was a considerable amount of inflammation with seepage of purulent material as the layers were dissected. When the carotid sheath was approached, aneurysmal dilatation was apparent, and it was decided to obtain proximal control of the carotid artery at the base of the neck. As this dissection was begun, spontaneous rupture occurred, resulting in severe hemorrhage which was arrested with pressure. The common carotid artery was isolated in a lesser involved segment just above the sternum and occluded with umbilical tape. The vessel was exposed in the infected area and found to be inflamed, necrotic, and very friable for a distance of several centimeters, with a defect which communicated with the aneurysmal space. It was considered impossible to repair this defect, nor was it thought advisable to utilize a graft. Accordingly, proximal and distal ligation was carried out. At the distal end, which was at the bifurcation, it was necessary to take large suture ligatures including surrounding tissues. Because the wound was large and gaping, Penrose

**From the Robert S. Marx Laboratories of the Department of Surgery, Wayne State University, School of Medicine, Detroit, Michigan.

†See Test Your Word Score Page 97.

drains were placed in the depth and it was partly approximated with silk sutures in the skin.

Pathologic Findings

Blood cultures were negative. Cultures of the wound grew out Staphylococcus aureus coagulase positive, Staphylococcus albus coagulase negative, and alpha streptococcus. The patient was treated with penicillin, streptomycin, chloromycetin, and later Staphcillin. Local wound care included hydrogen peroxide irrigations. He appeared to be improving; but two weeks later during a dressing change he began to bleed profusely from the distal end of the carotid artery, and on repeated exploration he was found to have additional necrosis of the vessels, requiring higher ligation of the internal and external carotid artery. He subsequently had a septic course with spiking temperatures of 104° and expired. At autopsy he was found to have interstitial pneumonia and septic changes in multiple organs. He had chronic pyelonephritis and generalized arteriosclerosis with massive infarction of the right cerebral hemisphere.

Case #2

A 74-year-old white male was admitted with a three-day history of headache, difficulty with speech, and weakness of his right upper and lower extremities. He was somewhat drowsy and confused. In 1949 he had had an abdomino-perineal resection for carcinoma of the rectum, at which time he also reportedly had a right nephrectomy and partial hepatectomy.

Physical Findings

Physical examination revealed a blood pressure of 165/115. Examination of the lungs and heart was within normal limits. There were incisional scars in the abdomen and a colostomy on the left. There was no nuchal rigidity, facial asymmetry, or motor impairment. He had a depressed corneal reflex, and the uvula deviated to the right. On the right side, he also had facial hypesthesia and hemiparesis, with decreased deep tendon reflexes.

Laboratory Studies

Basic laboratory studies were normal. Lumbar

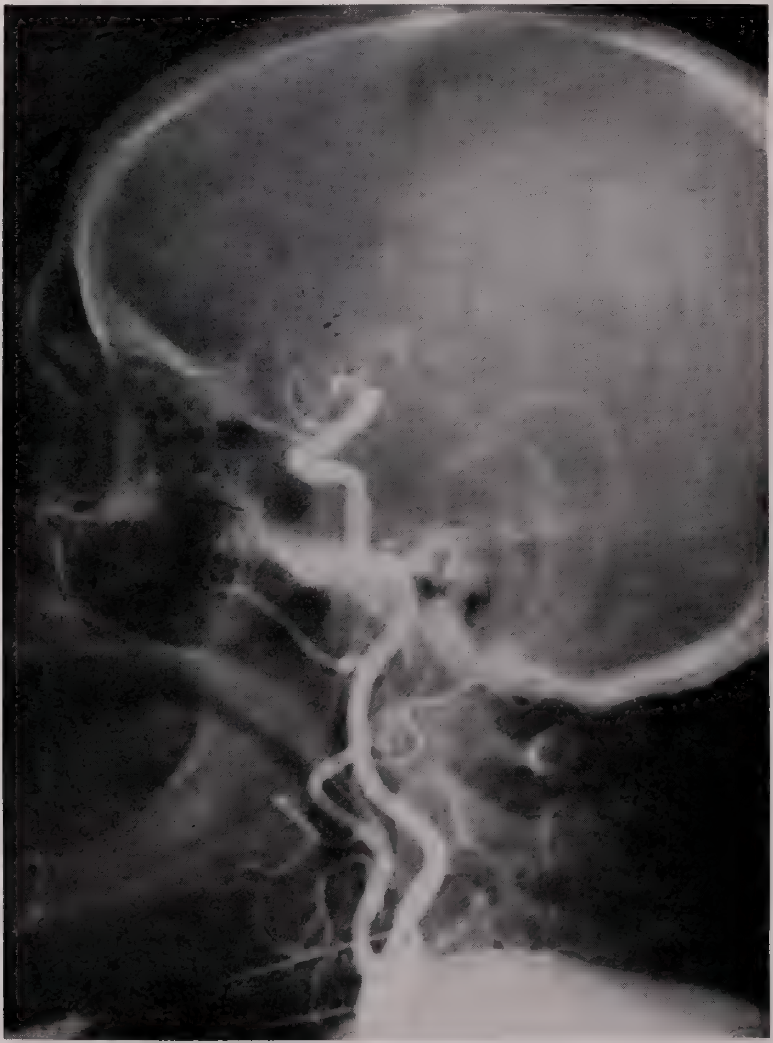

Fig. 1 — A roentgenogram taken at the time of the diagnostic carotid arteriography revealing injection of the left carotid sheath in Case 2.

puncture was done with an opening pressure of 120 mm. of saline and a closing pressure of 110. The fluid was bloody with a protein of 98 mgm% and a sugar of 50 mgm%. Skull films were normal. On chest x-ray, he was found to have cardiomegaly and a right pleural effusion. Electroencephalography was compatible with a subcortical lesion in the left hemisphere. Bilateral carotid arteriograms were done on February 6, using Renografin 60, with no abnormalities visible. However, injection of the carotid sheath was noted on the left (Figure 1).

Operative Findings

Eight days later he was noted to have a large tender mass involving most of the left side of the neck and a temperature of 101°. As a result of our previous experience, the possibility of an aneurysmal abscess was considered. The neck was explored and at the start of the procedure the carotid artery was exposed and controlled with umbilical tape at its emergence into the neck. Distally, the internal and external carotid arteries were similarly isolated. As the incision was carried into the mass, necrotic, purulent exudate escaped from the wound edges. A large excavation was encountered which communicated with an opening in the common carotid artery, a long segment of which was necrotic and friable and could not be preserved. The infection invaded extensively into the surrounding area with alteration of the tissues. Proximal and distal ligature of the carotid artery was accomplished. The wound was allowed to remain wide open, and the patient was treated with local dressings, irrigations, and systemic antibiotics. Postoperative neurologic examination was unchanged. In a few days a clean, granulating base developed and subsequently closed rapidly. There was no problem with additional bleeding. He was discharged after four weeks, to be followed in the Out-Patient Department.

Case #3

A 41-year-old negro male narcotics addict had been injecting paregoric into his femoral veins. He was admitted June 12, 1964, with a mass in his right groin which had been enlarging progressively for two weeks. There were multiple puncture scars in the extremities. Physical examination indicated a blood pressure of 120/60.

Physical Examination

Examination of the heart, lungs, and abdomen was within normal limits. There was a tender, indurated, pulsatile mass in the right femoral area extending from the inguinal ligament to the midthigh. Basic laboratory studies were normal, except for a white count of 18,000.

Operative Findings

On exploration, he was found to have extensive purulent inflammatory reaction in the tissues of the iliofemoral area. The entire upper thigh in its anteromedial aspect was indurated, edematous and

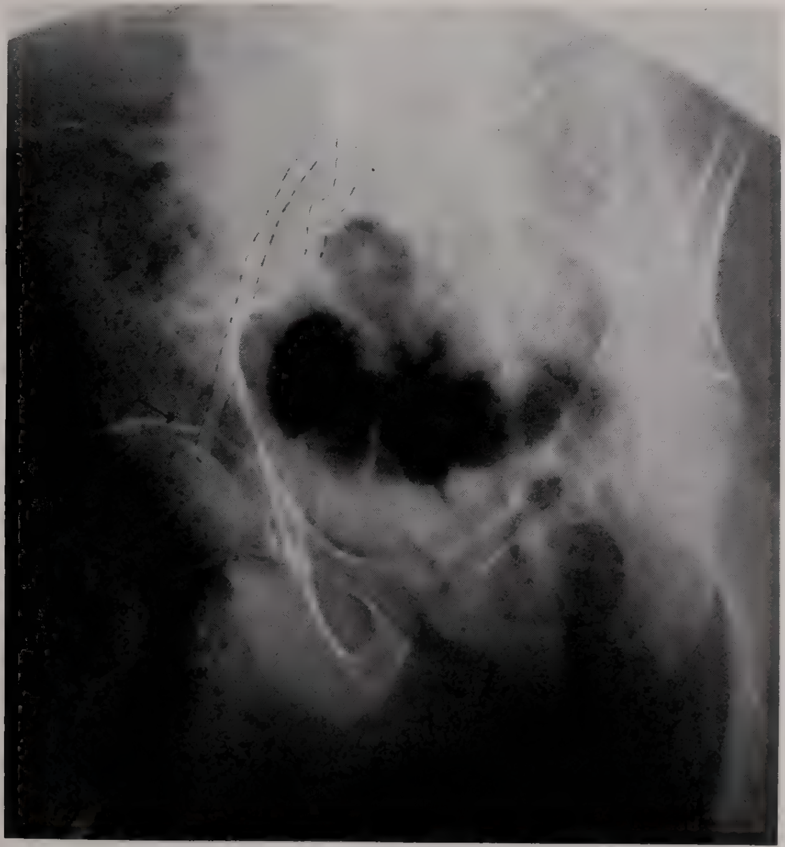

Fig. 2 — This x-ray was obtained following the initial surgical procedure. It shows termination of the dye column at the external iliac artery on the involved side. (Case 3)

tender. In this instance, prior arterial control was not obtained, and a large, infected, blood-filled space in communication with the femoral artery was entered, producing brisk hemorrhage. It was necessary to ligate the femoral artery above and below the site and to tie off the profunda femoris as well, leaving a defect in the vessel several centimeters in length. He was able to maintain circulation and viability in the extremity and the wound was healing satisfactorily on discharge from the hospital.

A reconstructive procedure was planned. However, this man went elsewhere. Figure 2 shows the arteriogram obtained in that hospital. A bypass graft was inserted which subsequently clotted. He is being followed currently by this surgeon.

Case #4

This patient was a 34-year-old negro male with a twenty-year history of drug addiction. He was admitted with a large, tender, painful mass in his right groin which had been present for one week. The history was otherwise not contributory. On physical examination, his blood pressure was 140/90, temperature 101°, pulse 110. Examination of the heart, lungs and abdomen was unremarkable. Laboratory studies were within normal limits.

Operative Finding

On exploration he was found to have a hematoma beneath the external oblique muscle just superior to the inguinal ligament. This collection extended deep into the ligament, and on the removal of the blood clots, arterial bleeding ensued, which was controlled with pressure. The incision was enlarged, and the iliac and femoral arteries were exposed and occluded proximally with an arterial clamp. Distally the vessel did not bleed. On removal of the remainder of the hematoma, the external iliac artery was found to be necrotic and destroyed for a distance of 5 cm. The artery was ligated where it had been entered. Drains were placed in the wound and the fascia loosely approximated.

Culture revealed the presence of aerobacter aerogenes, gamma streptococcus, Staphylococcus albus coagulase negative, and pseudomonas. His postoperative course was satisfactory under treatment with antibiotic and local care. He has since been lost to follow-up.

Discussion

The term "mycotic" was first used by Osler in 1885 to denote those aneurysms which result from septic emboli originating in vegetations of bacterial endocarditis.[5,7,10,12,15] Infection reaches the vessel wall either via the lumen or through the vasa vasorum.[4,13,14] Local sepsis can also affect the arterial wall either by lymphatic spread or more directly from an adjacent infective process.[3,4,13,14] The cases we have presented must be considered examples of this latter category.

Error in Technique

There seems little question that in our patients infection was introduced by means of contaminated instruments or materials, and that it played a major role in the disease process. Certainly this is not surprising where addicts are injecting themselves with opiates. However, the two cases in which infected aneurysm followed angiography are rare complications of this procedure and must be ascribed to a major break in technique.

Chemical Necrosis

Any contamination under these circumstances is augmented by the additional factor of chemical necrosis. When *contrast material* used in arteriography escapes into the vessel wall or into the surrounding area, it is known to be irritating and may result in necrosis and a corresponding inflammatory reaction, regardless of any superadded infection.[11] Similarly, in the addicts who were injecting concentrated paregoric, we surmise that the substance was inadvertently deposited into tissues near major vessels, or perhaps into the arterial wall itself. One of the ingredients is *camphor,* which has been used to produce necrotizing abscess in experimental animals. The resulting dead tissue offers little local defense against the spread of infection and may provide a good culture medium. Contaminating organisms can thrive not only on dead tissue, but also on extravasated blood. Some degree of extravasation must be expected with intravascular injection, but presumably it is greater if for some reason the arterial wall is torn. In one of these cases we do have evidence of intramural injection. Injury could occur either from the needle itself, from introduction of chemicals into the wall, or by the force of intramural injection.

Extravasated Blood

Extravasation of blood opens up a space for infection and in itself may cause some degree of necrosis of tissue. In this connection, one must consider the possibility that the infection was preceded by the development of a false aneurysm which results from arterial injury and has been reported to occur on rare occasions as a complication of percutaneous arteriography.[9,11,16] However, a false aneurysm is contained by a wall formed by compressed tissues in which there is organization.[5,6] In the cases we have reported, no such structure was recognized. It may well be that the time interval between the injection and the onset of these abscesses was too short for organization to occur. There is some question whether it is possible for organization to take place in a fulminating infection of this kind in which spreading factors and various enzymes may be released which can effect further tissue breakdown. These lesions appeared to be most closely akin to infected pulsating hematomas in which encapsulation is lacking.[5,8]

Treatment

Confronted with a rapidly enlarging mass with evidence not only of local sepsis, but also of generalized toxicity, drainage is the method of choice. The problem of differentiating between an abscess and an infected aneurysm may arise, as is illustrated by two of our cases. Others have reported similar difficulty.[1,5,17] We see a number of examples of abscess and thrombophlebitis in addicts. The presence of infection in the mass causes the entire area to be indurated so that the expansile nature of pulsations may not be appreciated.

Our experience suggests that the widest possible drainage is indicated in these lesions. Proximal and distal ligature of the vessels involved may be necessary to prevent exsanguination. Modern techniques would prompt one to try immediate reconstruction. In certain circumstances when critical arteries are involved, Smith, Szilagyi, Colville and others have practiced the use of autogenous vein grafts tunneled through uninfected tissue joining healthy artery above and below the defect.[14] The cases reported by these authors were localized lesions arising as embolic phenomena from sepsis elsewhere. Yet even in such cases where the pathologic process was relatively confined, grafting procedures in the involved areas often have been unsuccessful. We also have had some experience with mycotic aneurysms secondary to septic embolization in which there is a definite capsular structure. These usually have been of a more chronic duration — occasionally several months or years. Here both ligation of the artery and reconstruction with a venous graft have been employed to advantage. In our present series of cases, however, we were not dealing with lesions which were fairly well localized, as in true mycotic aneurysms. We were faced, rather, with such extensive tissue destruction and inflammation that it was thought unwise to place a graft in the vicinity.

It is interesting to note that in these patients ligature of major vessels did not result in gangrene. The addicts were young individuals and in addition may have developed sufficient collateral circulation as the aneurysm progressed. The two men who had difficulty following carotid angiography were orginally admitted with ischemic problems and may have previously developed collateral circulation.[2] In these instances, also, the original arteriosclerotic obstruction was on the same side as the subsequent infectious process.

Summary

Four cases are presented of infected aneurysms involving carotid and femoral arteries, which followed administration of angiographic media or, in addicts, concentrated paregoric mixtures.

We believe the lesions we have encountered resulted from a combination of infection, chemical necrosis, and extravasation of blood.

Treatment of these lesions involves incision, ligation, and wide drainage.

This entity differs from mycotic aneurysm in that the process is much more acute, and the patient presents with all the signs of an abscess. Vascular reconstruction was not deemed feasible.

Addendum

Two other patients with lesions similar to that described above were recently admitted to the surgical service. A 50-year-old diabetic was hospitalized elsewhere, August 30, 1965, with left hemiparesis and evidence of brain stem ischemia. Arteriograms revealed narrowing of both internal carotid arteries and of the left vertebral artery. On September 15, 1965, an endarterectomy was performed on the left common and internal carotid arteries, using a polyethylene bypass. The arteriotomy was closed primarily with 6-0 Tefdek.

Five weeks later she presented for the first time to our hospital, febrile, with an inflamed, expanding, pulsatile mass in the left side of her neck deep to the healed incision. There was blackening of the skin adjacent to the scar with frank gangrene of its lower end. Her breathing was impaired due to tracheal compression. The diagnosis of an aneurysmal abscess was made, and rupture was considered to be imminent. The patient was taken immediately to the operating room and a supraclavicular incision made, through which it was possible to obtain control of the carotid artery without entering the abscess. The mass was then incised and a foul-smelling blood clot was evacuated, revealing an aneurysmal abscess, identical in many respects to those we have described. There was extensive necrosis of the common carotid artery at its bifurcation, the site of previous surgery, with a hole in the vessel wall surrounded by brownish debris. Brisk arterial back bleeding arose from the internal and external carotid arteries. It was necessary to ligate them and the common carotid arteries at sites where the vessel would hold a suture. The wound was packed. Postoperatively she had extension of her brain damage and was unresponsive. Beta hemolytic streptococcus was cultured out.

This case points up the necessity of establishing blood flow in critical arteries such as the internal carotid. It may be that in the future it would be advisable to try to insert a vein graft even to the divided internal carotid artery, despite the surrounding abscessed tissue.

The sixth patient, a 58-year-old negro male was admitted November 12, 1965, complaining of increasing pain and swelling in his left groin, beginning one week previously. He had been addicted to heroin for 35 years and had recently been injecting drugs into the left femoral vein. Examination revealed a large indurated mass in the left groin measuring 5 to 6 inches in diameter, which appeared to pulsate. A thrill was palpable over the area and a bruit could be heard on auscultation. There was a necrotic ulcer in the center which was leaking blood and pus. The patient, although febrile, refused treatment and signed out against medical advice. However, on November 15, he returned with increased pain and swelling and an enlarged girth of the entire left thigh. No pedal pulse could be palpated on the left. A retrograde aortogram was obtained through the right femoral artery. It revealed a false aneurysmal sac arising from the common femoral artery, with delay and reduction of blood flow into the left leg. The left hypogastric vessel did not opacify. Arteriosclerotic changes were present throughout.

The patient was taken to the operating room and the abscess cavity was opened and drained of considerable clots and necrotic debris. Bright red bleeding ensued from the femoral artery at its bifurcation where the anterior wall was missing for a distance of two inches. It was necessary to ligate the common femoral artery proximally and the superficial and deep femoral arteries distally. The cavity was large and extended proximally toward the pelvis and distally for a distance along Hunter's canal; posteriorly it reached around the femur. The femoral vein had become all but dissolved in the abscess. The wound was left open. The patient was receiving high doses of antibiotics at the time of surgery. Postoperatively, he continued to have a warm left foot with a moderately good capillary flow. This patient resembles the other two with femoral aneurysms. We considered passing a bypass from the iliac to the femoral artery through the obturator foramen. However, drug addiction had destroyed his veins and we would have had to use a prosthetic graft. His infection, however, extended so widely that we considered the chances of avoiding infection to be too slight to warrant this procedure, especially as triple ligature of the femoral vessels in the other cases did not result in gangrene.

A New Diagnostic Test for Coronary Artery Disease

Using A Coincidence Counting System

ALBERTO COHEN, M.D.*
EIDE-DITMAR LUBS, M.D.**
EDWARD J. ZALESKI, M.D.†
RICHARD J. BING, M.D.‡
Detroit, Michigan

THE DIAGNOSIS of coronary artery disease can usually be made on the basis of clinical history alone. In doubtful cases other procedures are necessary, such as the stress electrocardiogram.[1-3] It is well recognized, however, that an abnormal electrocardiogram may exist in the presence of a normal heart. T-wave inversion or bundle branch block may or may not be an expression of coronary heart disease. These changes, in addition to pathological Q-waves, may also be present in some cardiomyopathies in which the coronary arteries are normal.

Visualization of the coronary arteries by coronary arteriography is at the moment the only method to ascertain more clearly the extent of the disease of the coronary arteries.[4,5] In many individuals the cause of chest pain is obscure, and coronary arteriography is the only means of excluding coronary arteriosclerosis. Even so, coronary arteriography has certain disadvantages: The technique is sometimes difficult and poses discomfort to the patient. The procedure necessitates intra-arterial catheterization and, with the method of Sones,[2] intubation of the coronary arteries. Complications, although rare, are cardiac arrhythmias and myocardial ischemia.[5-7] Technical difficulties sometimes preclude good visualization of the coronary arteries and a trained team is required. In addition, it has been observed that many affected segments of the coronary arteries escape radiologic detection.[8]

For these reasons a procedure which could be performed without discomfort or hazard to the patient and which could be routinely carried out would be desirable. The present report deals with the results obtained in the recognition of coronary artery disease, using a coincidence technique and a positron-emit-

ting isotope, rubidium^{84} The principle of the test consists of measuring the coronary blood flow using this isotope and comparing the effect of nitroglycerin on coronary blood flow. No attempt is made in this report to describe the technique in detail, the concepts involved in this method, and the mathematical analysis of the data obtained. These have been published in separate communications.[9-11]

Coincidence Counting Method

In the coincidence counting method, pulses are recorded which result from the annihilation of positrons (positive charged electrons, beta-plus) occurring directly between a coincidence pair of detectors. A positron travels a few millimeters inside the body before annihilation with a negative electron, thereby producing two gamma photons directed 180 degrees apart. This is in contrast to the so-called singles technique, which is employed, for example, when rubidium^{86} is used. The singles technique requires heavy lead collimation* around the crystals to limit its field of view; in contrast, in the coincidence method shielding is simplified.

Advantages

Advantages of the coincidence over the singles method are elimination of background noise and a simplified mechanical design. In addition, the activity of the positron-emitting isotopes is in direct proportion to its tissue content and is not a function of the distance of the tissue from the counter, as it is when the singles method is used. The counting rates from structures surrounding the heart do not interfere with the apparatus employed here, and efficiency of the coincidence system is about five times greater than that of a system employing rubidium^{86}. One of the main advantages of the method is that it permits separation of radioactivity of the heart muscle from that of the surrounding tissue. In the apparatus used in these tests two pairs of crystals are used: one pair placed in front and behind the heart respectively; the other symmetrically placed over the right side of the chest (Figure 1). The difference in transmission between the right and the left coincidence counting system is continuously equated electronically and corrected for the presence of the heart and the resulting loss of transmission. This difference in transmission is found by placing a 3-inch stainless steel container with a known dilution of rubidium^{84} successively under the right and left coincidence counters over a predetermined area. The instrument is then electronically aligned to correct for tissue density over both sides of the chest. In addition, a well counter is used, through which arterial blood is drawn at a constant rate. The ratio of efficiency between the coincidence counting pairs and the well counter is less than 1:1,000. Since, in addition, the specific activity in the blood is very small, the disintegrations of rubidium^{84} emanating from the cardiac cavities can be neglected.

The Technique

The myocardial scanning coincidence pair is directed over the left precordium, using an aiming device. The position of the heart

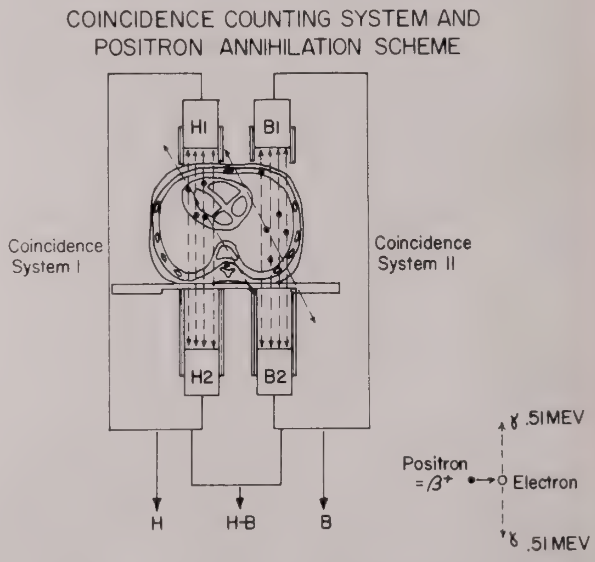

Fig. 1 — Diagrammatic representation of the coincidence counting system and positron annihilation. The two pair of detectors are shown (H_1, H_2 and B_1, B_2). The precordial activity (H) is subtracted electronically from the right chest activity. The difference (H-B) expresses the myocardial radioactivity alone. The right side of the graph shows that when a positron ($\beta+$) collides with a negatively charged electron, two gamma photons with a peak energy of 0.51 MEV are produced. When these gamma photons strike simultaneously the upper and lower detectors of the coincidence pair, a pulse is recorded.

*See Test Your Word Score Page 97.

is ascertained by roentgenography or fluoroscopy of the chest in the test position. The right side counting pair is placed symmetrically over the right hemithorax above the area of projection of the liver to observe the uptake of rubidium in the chest exclusive of the heart and the liver dome. Uptake of rubidium^{84} by the heart muscle is then expressed as the difference between the left and right sides counting systems (H-B). The apparatus is equipped with a strip chart recorder which prints directly the activity of the left chest (H), the right chest (B), and the difference between these two activities (H-B). The activity of arterial blood as measured in the well counter (A) is also recorded (Figure 1).

After placing the patient under the coincidence counting pairs, 0.4 microcuries of rubidium^{84} per lb. of body weight in 30 ml. of saline are infused intravenously by means of a special motor-driven syringe at a speed of 1 ml. per minute. Simultaneously, arterial blood is drawn from a needle inserted in the brachial or femoral artery. The arterial blood is drawn at a constant speed (7 ml/min.) through a Radicoil inserted into a well counter.

The calculation of the coronary blood flow is based on the Fick principle[12] in which flow is equal to the ratio of the myocardial uptake of rubidium^{84} and the coronary arteriovenous difference of concentration of the isotope. This can be expressed as:

$$1. \qquad \text{Flow} = \frac{dk/dt}{A\text{-}V}$$

where, dk/dt is the myocardial uptake of rubidium^{84} (disintegrations/min.^{2}) and A and V are the radioactivities in the arterial and coronary venous blood (disintegration/ml. x min.) Dividing numerator and denominator in this equation by A, one obtains:

$$2. \qquad \text{Flow} = \frac{\frac{dk/dt}{A}}{\frac{A\text{-}V}{A}}$$

in which, $\frac{dk/dt}{A}$ is the myocardial clearance of rubidium^{84} and $\frac{A\text{-}V}{A}$ is the extraction ratio of rubidium^{84} by the heart. Consequently,

$$3. \qquad \text{Flow} = \frac{\text{Clearance}}{\text{Extraction ratio}}$$

To calculate the coronary blood flow from the myocardial clearance of rubidium^{84}, it is essential to know the influence of coronary flow and heart rate on the extraction ratio. In previous communications[9-11] it was shown in 11 isolated perfused dog hearts and in five patients, in whom the coronary sinus was intubated, that the myocardial extraction ratio declines monotonically with time; changes in flows or heart rate do not alter the slope of the extractions ratio. As the coronary sinus (V) is not intubated during the test, extraction ratio is not known. Based on the above concepts, it is possible to calculate the coronary blood flow by the logarithmic extrapolation of the myocardial clearances to zero time. At this time the radioactivity of the venous blood may be assumed to be zero and that therefore the extraction ratio equals one. This concept has been confirmed experimentally in nine isolated perfused dog hearts with an accuracy between the calculated and observed flows of 93%.[10]

Consequently at time zero:

$$4. \qquad F = \frac{\frac{dk/dt}{A}}{\frac{A\text{-}O}{A}} \quad \text{or} \quad F = \frac{dk/dt}{A}$$

Further details for the calculations of the coronary blood flow in absolute units (ml/min.) are reported in other communications.[9-11]

Calculations were performed entirely by objective analysis carried out with a digital computer. Computer calculations included computation of the myocardial uptake of rubidium^{84}, the first derivative of the uptake, the myocardial clearances, and the coronary blood flow, as well as their standard deviations.

Selection of Patients

The studies were carried out on 10 patients with and on 12 without coronary artery disease. Criteria for the presence of coronary artery disease were a combination of the following: coronary arteriography revealed narrowing and beading of the coronary arteries, a history of recent infarct as substantiated by electrocardiographic and enzymatic studies was present, and a previous infarct was suspected on the basis of history and electrocardiographic findings. The patients ranged in age from 22 to 74 years, nine of them females. Two tablets of nitroglycerin (each 1/150 grain) were administered sublingually after a control period of seven minutes, and the coronary blood flow was followed during one or two periods of seven minutes each after administration of the drug.

Results

In 12 individuals without coronary artery disease the administration of nitroglycerin resulted in a rise in coronary blood flow in six during the first period following the administration of the drug; in eight it remained elevated or increased further during the second period (Figure 2, Table 1). The increase averaged 38 per cent ($P < 0.05$) during the first period and 70 per cent ($P < 0.005$) during the second. In contrast, with the exception of one individual (J. K.), the coronary blood flow failed to rise in nine patients with proven coronary artery disease (Figure 2, Table 2). The average decrease was −14 per cent ($P < 0.025$).

These results demonstrate that nitroglycerin increases the coronary blood flow in patients without coronary artery disease but not in those with coronary artery disease.

Comments

The effect of nitroglycerin as described above is in agreement with several publications.[13-15] The action of nitrites in relieving angina pectoris has been known since 1867, when Brunton[16] described the effect of amylnitrite on a patient suffering from angina pectoris. The effects on the cardiovascular system which bring about the relief of pain are, however, still debated. In dogs nitroglycerin increases coronary flow and decreases cardiac work.[17] A similar effect has also been demonstrated in man. Brachfeld and associates found that in normal man nitroglycerin increased coronary blood flow and myocardial oxygen consumption without elevating the oxygen tension in coronary vein blood.[14] There is evidence that nitroglycerin fails to increase coronary flow in patients with coronary artery disease.[13] Hollander and associates found that nitroglycerin did not increase the rate of clearance of radioactive

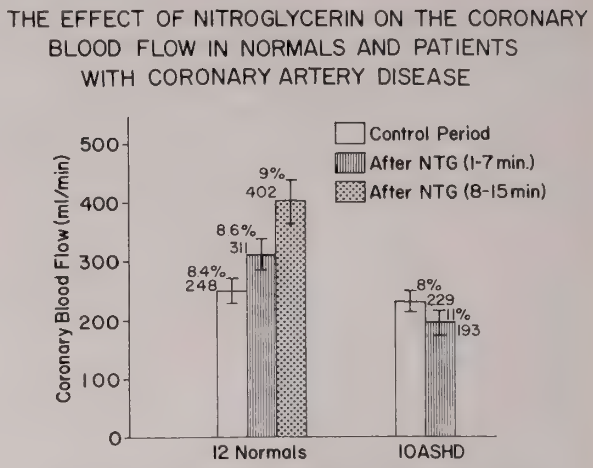

Fig. 2 — The mean coronary blood flow in individuals with and without coronary artery disease before and after sublingual administration of nitroglycerin is shown. It is seen that the coronary blood flow increases in normals but not in patients with arteriosclerotic heart disease.

sodium iodide from the heart muscle of patients with angina pectoris.[18] Similar results were obtained by others using the nitrous oxide and radioisotope methods.[13-15] It is likely that in normal hearts coronary blood flow increases with nitroglycerin because of a fall in coronary vascular resistance. Although the peripheral coronary vascular resistance may fall in arteriosclerotic patients this effect cannot become manifested because of impediment to flow in the large coronary vessels.[19] Dynamic studies on the action of nitrites have shown that there is a fall in central venous pressure with a decrease in cardiac output and left ventricular work.[13,14,20]

Conclusions

The results reported here confirm the findings of others that nitroglycerin increases coronary blood flow in normal individuals but not in patients with coronary artery disease. This is the basis for the test described here, which differentiates between these two groups. The procedure involves the use of a positron emitter and the coincidence counting system. The advantages of this test are its technical simplicity and objectivity. Catheterization is not necessary and the test lasts no longer than 30 minutes, involving only intravenous infusion of the isotope and an arterial puncture. The data are then processed by a computer which calculates the coronary blood flows in ml/min., together with the standard deviations and the significance of the change in flow prior to and following the sublingual administration of nitroglycerin. The procedure does not permit the measurement of instantaneous changes in the flow because of the high statistical errors when periods of less than five minutes are used.[9-11] It does permit differentiation of patients with and without coronary artery disease with a reasonable degree of accuracy.

Pyoderma Gangrenosum

Treated with Sulfone Drugs

PYODERMA GANGRENOSUM is a rare, chronic, ulcerative skin disease which was first described by Brunsting et al.[1] in 1930. The lesions begin as cutaneous abscesses which rapidly break down to form large, peripherally spreading ulcerations with a distinctive purple-red, edematous, and undermined border. The original authors stressed the frequent association of the skin lesions with an underlying chronic debilitating disease, particularly chronic ulcerative colitis.

Later reports confirmed pyoderma gangrenosum as a clinical entity and also noted its association, not only with ulcerative colitis, but with arthritis, foci of infection, hypogammaglobulinemia, and a dermatitis herpetiformis-like vesicular eruption as well.[2-4] In addition, many cases of pyoderma gangrenosum have now been recorded in which no underlying disease state was found.

The disease has a chronic course and during active stages the patient's skin seems to be hypersensitve to both local trauma and to the ingestion of iodides. New lesions may develop at the site of minor or casual skin trauma, while the ingestion of iodides may cause marked aggravation and generalization of lesions.

Oral and parenteral corticosteroids as well as sulfonamides, sulfones, and gammaglobulin have been used effectively in treatment of the disease.[2-5] Control of any underlying condition, such as ulcerative colitis, is of utmost importance since there may be a correlation between the activity of the colitis and the skin lesions.

Case Reports

The purpose of this paper is to report on the treatment and course of two patients with pyoderma gangrenosum, particularly with respect to the use of sulfone drugs in the management of the disease.

Case #1

A 60-year-old white female patient was first seen on December 27, 1962. She was sent to us for follow-up treatment of pyoderma gangrenosum after having been hospitalized at the Mayo Clinic from September through December of 1962.

Past History

The original lesion had appeared as a "pimple" on the abdomen in August 1958. This lesion ulcerated spontaneously and slowly spread to form a large linear ulceration on the left lower quadrant of the abdomen (Figure 1). Subsequently, similar but smaller ulcerations appeared on the right thigh, right shin, and left calf.

The patient had been followed at Henry Ford Hospital from August 1959, through August 1962, being hospitalized twice during that period. Pyoderma gangrenosum was diagnosed, but extensive investigation failed to reveal any underlying ulcerative colitis or infectious focus. During this period the patient experienced one episode of swelling and tenderness of the proximal interphalangeal joint of

the left ring finger without other evidence of arthritis. Roentgenograms of the finger showed only soft tissue swellings. A trial of salicylazosulfapyridine (Azulfidine) in November 1960 was discontinued, in spite of good initial response, because of development of a "typical morbilliform drug reaction" after nine days of therapy.

In September 1962, when hospitalized at the Mayo Clinic, the patient had four ulcerations varying in size from 17.5 by 5.5 cm. to 1.5 by 5 cm. located on the left lower quadrant of the abdomen, the left calf, the right thigh and the right shin. Oral methylprednisolone (64 mg. per day) was started in September 1962 with gradual healing of these ulcerations. However, in October and November 1962 the patient experienced two acute psychotic episodes requiring care on a closed psychiatric ward. The dose of methylprednisolone was gradually reduced to 21 mg. per day at the time of discharge from the Mayo Clinic in December 1962, when only the lesion on the right shin was active.

(Courtesy Dr. T. K. Burnham, Henry Ford Hospital, Detroit, Michigan).

Summary of Laboratory Studies

The value for hemoglobin, the leucocyte count, and the results of routine urinalysis were normal. Sedimentation rate varied from 50 to 65 mm. in one hour (Westergren). Serum electrophoresis showed an increased gammaglobulin (1.37 gm.). Cryoglobulins and macroglobulins were not present. Tests for rheumatoid factor, L.E. cells, and serologic tests for syphilis were negative. Values for blood urea, fasting blood sugar and uric acid were normal. Retention of dye in the sulfobromophthalein test was 0. Skin tests for blastomycin, Coccidiodin and histoplasmin were negative. Skin test for tuberculosis was positive. Repeated cultures of the lesions for bacteria, fungus, and acid-fast organisms revealed no significant pathogens. Microscopic examination of tissue from skin lesions on three occasions and tissue from the nodule on the left ring finger showed only chronic nonspecific granulation tissue. Proctoscopic examination was normal. Roentgenograms of the chest and colon were normal.

Subsequent Course

When first seen by the authors in late December 1962 diaminodiphenylsulfone[*] (Avlosulfon-Ayerst) 100 mg. twice daily was started and steroid dosage slowly tapered. In March 1963 all lesions were completely healed. Steroids and sulfone were then discontinued. The disease remained inactive until May 1964, when the patient developed a new ulceration

1.5 x 2 cm. on the mid-extensor aspect of the right arm. Diaminodiphenylsulfone 50 mgm. twice daily was started along with fluocinolone acetonide (Synalar) cream 0.01% topically with occlusive plastic film. The lesion healed slowly, and in September 1964 sulfones and topical fluocinolone cream were discontinued. Because of hemolytic anemia which may develop in patients on sulfone drugs supplemental iron salts were given along with the sulfone drug; however, no significant anemia developed. The patient has not required systemic steroids since April 1963, and there has been no recurrence of psychotic episodes, as of February 1965.

Case #2

A 59-year-old demolition engineer was first seen on April 10, 1964, because of chronic and recurrent nodular skin lesions over the fingers, knuckles, elbows, knees, soles, and buttocks.

Past History

The original lesion had been noted on the right buttock in 1957. This nodule underwent spontaneous ulceration and healing over an 18-month period. Similar lesions, some of which did not ulcerate, then began to appear over the extensor surfaces. The patient stated that at least one or two lesions had been present continually with intermittent flares for over seven years.

The patient also had diabetes mellitus of three years' duration. The disease was not well controlled because of his erratic use of oral hypoglycemic agents and also because his work as a wrecker kept him continually "on the road," making adherence to a diabetic diet difficult. He stated that he had had a sulfa-drug reaction in 1943. There was no history of asthma, hayfever, urticaria, ulcerative colitis or arthritis.

Physical Examination

Examination of the skin revealed numerous flesh-colored to slightly bluish nodules, varying in size from 0.5 to 3 cm. and situated on extensor surfaces of the fingers, knuckles, elbows, knees, and on the soles and buttocks. The lesions present on the soles and fingers were more bluish and hemorrhagic in appearance (Figure 2) and were painful at times, whereas all other lesions were asymptomatic. The remainder of the physical examination was normal.

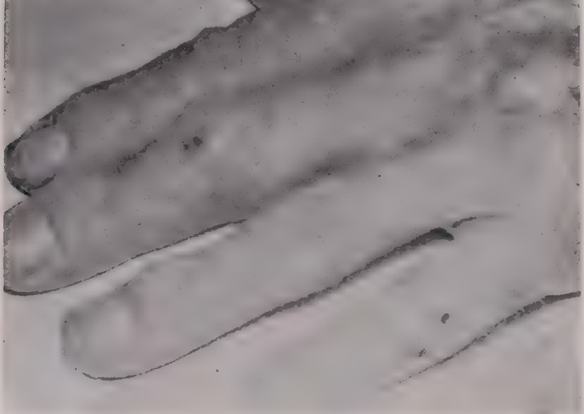

Fig. 2 — (Case 2) Nodules present on the fingers appearing somewhat bluish and hemorrhagic.

Course

The individual lesions appeared to start as areas of deep dermal induration which soon became more superficial and fluctuant and spontaneously exuded a viscid serosanguineous fluid. After draining the lesions healed rapidly with little scarring and without forming the typical chronic ulcerations usually associated with pyoderma gangrenosum. At times some of the indurated areas appeared to resolve spontaneously without becoming fluctuant and without draining.

On June 2, 1964, the patient was started on oral saturated solution of potassium iodide because of the suspicion of sporotrichosis. After taking only 10 drops of potassium iodide solution he experienced a dramatic and profound flare, with marked increase in size and considerable pain in all existing lesions, and with development of new lesions. He was hospitalized at Detroit Memorial Hospital on June 6, 1964.

Laboratory Studies

The value for hemoglobin was 14.8 gm. The leucocyte count was 7900 with 11% eosinophilia. The sedimentation rate varied from 40 to 74 mm. in one hour (Westergren). Routine urinalysis revealed a 4-plus reaction for sugar. The fasting blood sugar was 236 mg. per 100 ml. Other values were urea N 22 mg. per 100 ml., uric acid 5.4 mg. per 100 ml., protein-bound iodine 4.5 mcg. per 100 ml., serum bromide 0 mg. per 100 ml. Serologic tests for syphilis and tests for rheumatoid factor and cephalin cholesterol flocculation were negative. Serum protein electrophoresis showed: albumin 3.8 gm.; alpha-1 globulin 0.4 gm.; alpha-2 globulin 0.7 gm.; beta globulin 1.9 gm.; gammaglobulin 0.6 gm.; and total serum proteins 7.3 gm. per 100 ml. Repeated cultures from nodules for bacteria, fungus, and acid-fast organisms were negative. Smears of material aspirated from the nodules showed no organisms. Roentgenograms of the elbow, chest, colon and upper G.I. tract were normal.

Microscopic examination of skin from an early lesion on the right elbow in April 1964 showed only moderate nonspecific perivascular infiltrate. A second biopsy from a more active lesion on the left elbow in June 1964 showed moderate acanthosis of the epidermis and a diffuse granulomatous infiltrate in the corium consisting of histiocytes, lymphocytes, neutrophils and eosinophils, with some foreign body type giant cells. There were areas of necrosis with accumulation of polymorphonuclear leucocytes forming small abscesses. The findings were those of a chronic nonspecific granuloma (Figure 3). PAS and acid-fast stains were negative.

Subsequent Course

During hospitalization the diabetes was rapidly controlled with diet and insulin. The cutaneous lesions gradually decreased in size and became asymptomatic, and the patient was discharged from the hospital. The differential diagnosis considered at that time was iododerma, atypical pyoderma gangrenosum, and atypical acid-fast infection. The patient was placed on a halogen-free diabetic diet and on an oral hypoglycemic agent. In addition, sodium chloride 4 gm. per day was started in an attempt to remove remaining iodides from the body. However, the patient continued to develop new lesions in spite of elimination of iodides. On June 21, 1964, diaminodiphenylsulfone (Avlosulfon) 100 mg. twice daily and supplemental iron salts were started. Improvement in sulfone therapy was rapid and dramatic. Within two weeks all lesions had become quiescent except for a few scattered ones on the soles. Even these, however, were changed in that they appeared more superficial and vesicular. These vesicular lesions were not biopsied. After three weeks of sulfone therapy the skin was completely clear of lesions for the first time in seven years. This dramatic response to sulfone therapy was in conformity with the diagnosis of pyoderma gangrenosum.

---

*Diaminodiphenylsulfone (DDS, Dapsone) is available as Avlosulfon (Ayerst) in 100 mg. tablets.

When last seen in our office on August 7, 1964, the patient had remained free of skin lesions and was on diaminodiphenylsulfone 50 mg. twice daily and supplemental iron salts. A mild anemia (hemoglobin 11.7 gm.) was present.

The patient returned to work in Ohio and subsequently developed an acute penumonia. He was hospitalized and died there on August 17, 1964.

Post-mortem Findings

A post-mortem examination was performed at Miami Valley Hospital, Dayton, Ohio. The gross and microscopic findings were reviewed by the authors (microscopic sections courtesy of Dr. Eric Wenyon, Dayton, Ohio). The cause of death was an acute necrotizing, purulent lobar pneumonia. No organisms were seen in routine sections of the lung nor in those stained for acid-fast organisms and fungus. Skin lesions were not present at the time of death, and therefore no skin specimens were taken. Other significant microscopic findings were: moderate coronary atherosclerosis, centrolobular necrosis of the liver secondary to chronic passive congestion, localized chronic pyelonephritis with marked arteriolar nephrosclerosis.

The cause of death, lobar pneumonia, was felt to be unrelated to the patient's prior skin disease.

Comment

It is now generally accepted that pyoderma gangrenosum is not primarily bacterial or infectious in origin. A hypersensitivity reaction analagous to the Schwartzman phenomenon has been suggested[6] to explain those cases of pyoderma gangrenosum associated with an underlying systemic disease or infectious focus. An autoimmune mechanism has also been postulated, based on some violent antigen-antibody reaction.[5] However, the etiology of the disease remains obscure. The histology of pyoderma gangrenosum is not diagnostic and (as in our two cases) usually shows an ulceration with an associated chronic nonspecific inflammatory infiltrate and an increased number of blood vessels in the corium.[7]

Case 1 presented typical lesions of pyoderma gangrenosum with no underlying disease. The lesions responded well to oral steroid therapy; but this therapy induced two acute psychotic episodes. Good response to oral administration of sulfones permitted rapid tapering of steroids without exacerbation of skin lesions and without recurrence of psychosis. A subsequent flare of the condition responded well to treatment with sulfone drugs and topical steroids alone.

Case 2 presented unusual cutaneous lesions unassociated with other systemic disease. The lesions began as deep abscesses over extensor surfaces which drained and healed without forming spreading ulcerations. The course of the disease was marked by two very dramatic occurrences which we feel confirmed the diagnosis of an unusual variety of pyoderma gangrenosum: (1) A profound flare of all lesions after ingestion of a minimal dose of saturated solution of potassium iodide. (2) An excellent and rapid response to sulfone therapy.

The finding that this patient's skin lesions appeared superficial and vesicular at times led us to believe that this patient might represent a cutaneous phase of the pyoderma gangrenosum syndrome that lies somewhere between the dermatitis herpetiformis-like erup-

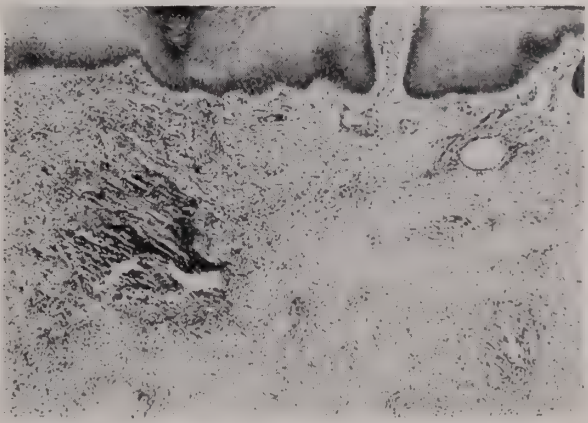

Fig. 3 — (Case 2) Section from active nodule on left elbow showing a diffuse granulomatous infiltrate in the corium. There are areas of necrosis with accumulation of polymorphonuclear leucocytes forming small abscesses. (Hematoxylin and eosin; X60)

tion which has been reported and the more typical undermining ulcerative lesions.

The sulfone drugs have been used effectively in the treatment of leprosy, dermatitis herpetiformis, subcorneal pustulosis and pyoderma gangrenosum.

The sulfones and the sulfonamide drugs have a similar chemical structure but differ in the manner in which sulfur is linked to atoms other than oxygen. In the sulfone drugs these linkages are with two carbon atoms, while in the sulfonamides they are with one carbon and one nitrogen atom. Although the sulfonamides and sulfones are chemically related they do not seem to cross-react with each other.[8] This finding was confirmed in both our patients, since both had a history of sulfonamide allergy but tolerated sulfone drugs well.

Most sulfones are metabolized in vivo to the parent compound, diaminodiphenylsulfone,[9] which is apparently less toxic than other sulfones. We have, therefore, used only diaminodiphenylsulfone (Avlosulfon-Ayerst) in therapy.

Side effects of the sulfone drugs may include hemolytic anemia, cyanosis, methemoglobinemia, and symptoms of anoxia. Nausĕa, vomiting, anorexia, headache, paresthesia, nervousness, and drug eruption may sometimes occur. These toxic effects are readily reversible on withdrawal of the drug.

Since hemolytic anemia of varying but usually mild degree occurs in most patients taking sulfones, it is wise to administer supplemental iron salts and to recommend frequent rest periods for patients on long-term therapy.[9] In general the side effects of the sulfones tend to be temporary and rarely of a severe enough degree to contraindicate continued administration of the drugs.

Sulfone drugs are felt to be less toxic than sulfapyridine in the long-term treatment of diseases such as pyoderma gangrenosum and dermatitis herpetiformis.

Summary

In the treatment of pyoderma gangrenosum it is suggested that sulfone drugs, particularly diaminodiphenylsulfone (Avlosulfon), are effective in the long-term care of this disease.

The sulfone drugs do not produce allergic cross reactions with the sulfonamides and appear to be well tolerated in patients sensitive to sulfonamides.

The Penalty of Overweight

The inadequacy of pulmonary ventilation in the obese results in decrease in arterial oxygen saturation and an increase in carbon dioxide retention. This derangement can cause somnolence, muscular twitching, cyanosis, secondary polycythemia, and hypertrophian failure of the right ventricle.

Massive Intracerebral Hemorrhage

J. L. CHASON, M.D.*
WILLIAM F. MAHONEY, M.D.*
JAMES W. LANDERS, M.D.*
Detroit, Michigan

CEREBRAL VASCULAR diseases are a major health problem in the United States, ranking as the third leading cause of death in adults.[1] In this country, in 1962, approximately 200,000 people died of these disorders,[1] and it has been estimated[2] that ten times the number who die each year are living victims of cerebral vascular diseases. Increases in the aging population add to the group most susceptible to these conditions.

One of the most common, yet least understood, manifestations of these diseases is massive cerebral hemorrhage. This study presents a brief analysis of the clinical features, morbid anatomy, and theories of pathogenesis of spontaneous massive cerebral hemorrhage, based on patients examined at autopsy in a large emergency hospital.

Materials and Methods

From June 1952 through June 1961, at Detroit General Hospital, 5,799 autopsies were performed on patients over the age of ten. The brain was examined in all but 316 patients, in none of whom was there a question of cerebral hemorrhage.

In all instances, the brain was fixed in 10% formalin at the time of autopsy and sectioned following fixation. Routine and selected paraffin-embedded sections, stained with hematoxylin and eosin, were examined in every case.

The following items, when recorded, were tabulated from each clinical record:

1. Age, sex and race
2. History of hypertension
3. Time from hospital admission to death
4. Characteristics of cerebrospinal fluid
    a. opening pressure
    b. presence of blood
    c. xanthochromia

The autopsy protocols were examined for evidence of hypertensive cardiovascular disease, as reflected by left ventricular myocardial hypertrophy.

For the purposes of this study, massive intracerebral hemorrhage refers to spontaneous hemorrhage within the brain substance greater than 2.5 cm. in maximum diameter; hemorrhages secondary to trauma, blood dyscrasias, ruptured berry aneurysms** or vascular malformations are specifically excluded.

Results

There were 358 patients who died with

---

**See Test Your Word Score Page 97.

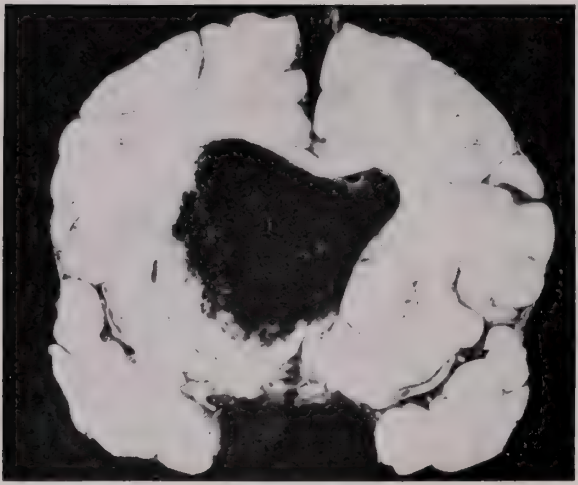

Figure 1

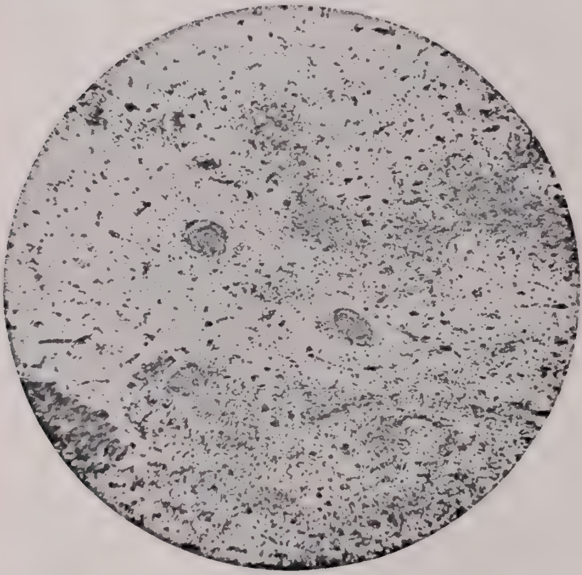

Figure 2

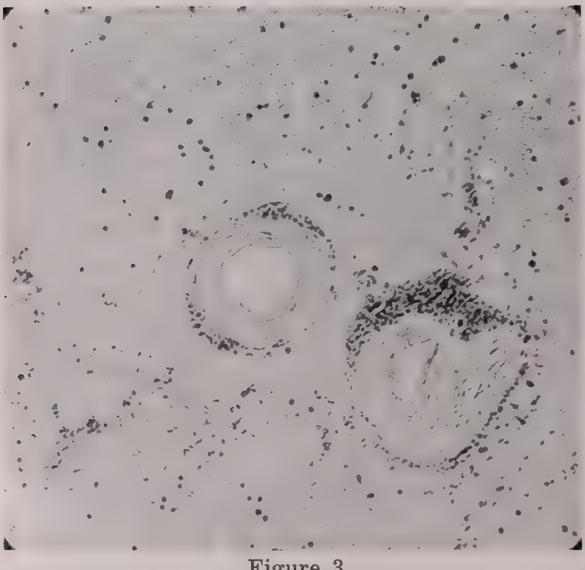

Figure 3

massive cerebral hemorrhage in this series, an over-all incidence of 6.2%. Analysis by age, sex and race is presented in Table 1. The incidence in females was 7.6% and in males, 5.3%; Negroes had an incidence of 8.5%, and whites, 4.4%. When sex and race were combined, the frequencies in descending order were: negro females, 9.4%; negro males, 7.7%; white females, 5.6% and white males, 3.8%.

A history of hypertension and/or anatomic evidence of hypertensive cardiovascular disease was present in all but two of the 358 patients.

Hypertensive Type

Three morphologically different types of hemorrhage occurred in these patients. The "hypertensive type" was found in 75.1%. In these, the brain about the hemorrhage was edematous and contained numerous petechiae (Figure 1). Microscopically, the arterioles at the margin of the hemorrhage showed sclerosis and hyalinization; many were necrotic and permeated or surrounded by red blood cells (Figure 2). About this zone sclerotic arterioles were surrounded by lakes of serum (Figure 3); and arteriolar sclerosis was widespread in the remainder of the brain.

Hemorrhage into Preceding Infarct

Hemorrhage into a preceding infarct accounted for 17.3%. In these, brain swelling about the hemorrhage was less marked, and satellite petechiae were few or absent (Figure 4). Microscopically, arteriolar necrosis was absent, arteriolar sclerosis less severe, and a pre-existing infarct of varying age could sometimes be identified in the margin of the hemorrhage (Figure 5).

Unclassified

Of the cases, 7.2% were labeled "unclassified." In these, although the gross appearance simulated the "hypertensive type," microscopic examination revealed a necrotizing arteriolitis without significant sclerosis or hyalinization (Figure 6).

Location of Hemorrhage

In 58% of the patients, the location of the hemorrhage was in the striate area (bilateral in eight patients); in 20.4%, elsewhere in the cerebral hemisphere (generally the white matter of one or more cerebral lobes); in 12.3%, in the pons; and in 9.2%, in the cerebellum. Rupture into the adjoining ventricle or subarachnoid space, usually the former, occurred in 92%.

Survival Time

The average age at death for the entire series was 56 years. When analyzed by race and sex, however, a significantly lower mean age at death is apparent for Negroes, and especially for negro females (Table 2).

Pons or Cerebellum

Although survival time was shortened when the hemorrhage was located in the pons or cerebellum, the duration of life seemed to correlate better with type of hemorrhage than with location (Table 3).

In Hypertensive Type

Thus, in patients with the hypertensive type of hemorrhage, 65% died within the first 24 hours; 91% were dead by the end of four days; and only two patients survived longer than 10 days.

In Preceding Infarct

By contrast, in patients with hemorrhage into a preceding infarct, 27% died the first day; 58% died in the first four days; and 24% survived beyond 10 days. Survival time for patients in the unclassified group was similar to that for patients with a hypertensive type of hemorrhage.

Elevation of the opening cerebrospinal fluid pressure (over 200 mm. of cerebrospinal fluid) was present in 82.4% of the 245 patients for whom this observation was recorded. The appearance of the cerebrospinal fluid was noted in 260 patients, and in 90% it was bloody and/or xanthochromic.

Discussion

Obviously, the over-all incidence (6.2%) of massive intracerebral hemorrhage is

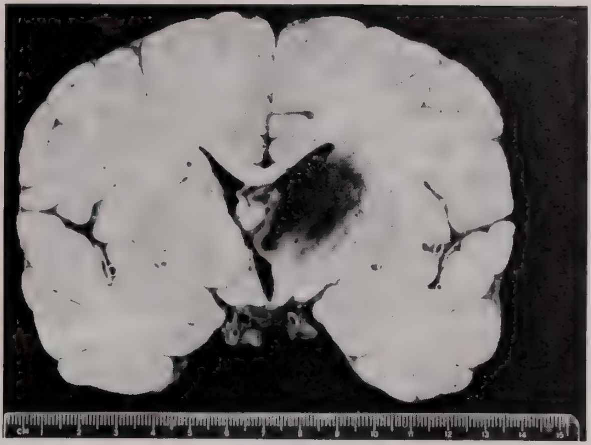

Figure 4

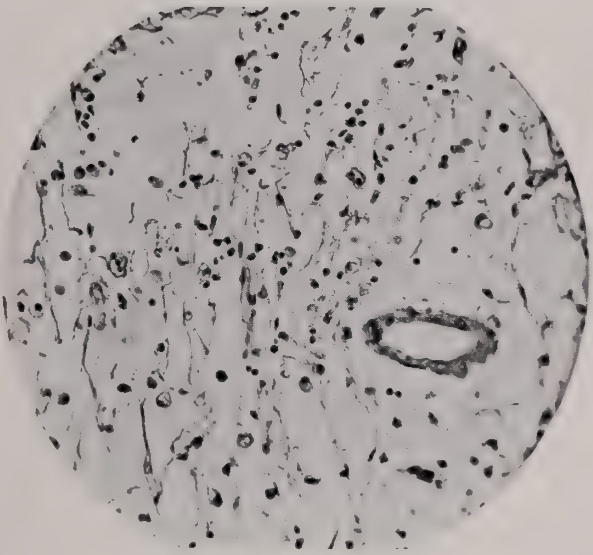

Figure 5

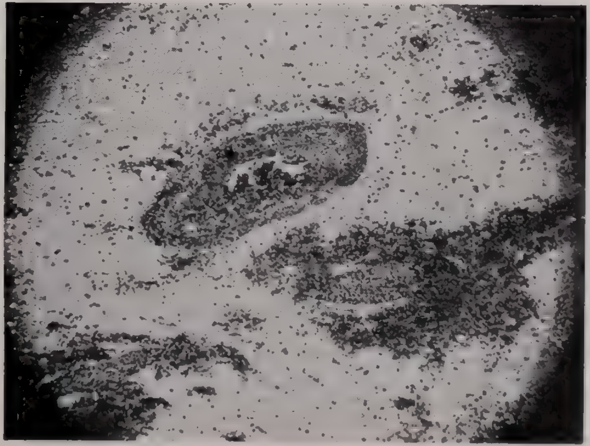

Figure 6

higher than is generally recognized as a cause of death, because of the concentration of such patients in an emergency hospital. Within the group of patients dying from this cause, however, there is no reason to suppose that the figures for sex and race incidence, which have been corrected for the numbers of each sex and race in the total series, are significantly distorted. It is, therefore, we believe, a valid observation that the occurrence of these lesions is more frequent in Negroes than in whites, and within each race a commoner occurrence in females than in males. It is also of interest that the age of onset is significantly lower in Negroes, and especially in negro females.

The morphologic appearance of the hypertensive type of hemorrhage suggests to us that it has its origin in simultaneous and successive rupture of numerous arterioles which, previously sclerotic as part of long-standing hypertensive disease, undergo necrosis for reasons unknown. The hemorrhage into a preceding infarct, on the other hand, probably results from rupture, under the stimulus of increased intravascular pressure, of vessels which are poorly supported externally because of infarction of the surrounding brain tissue. In addition to the differences in morphology and proposed pathogenesis, these two types of hemorrhage exhibit significant differences in length of survival following onset.

This autopsy study necessarily deals only

with patients dying with these disorders, and precise clinical distinction between the two main types of hemorrhage is probably not possible; nevertheless, we believe, on the basis of the evidence available, that prolonged survival following massive cerebral hemorrhage is largely confined to those patients suffering hemorrhage into a previous infarct.

Summary

Massive intracerebral hemorrhage occurred in 358 (6.2%) of 5,799 consecutive autopsies in a large emergency hospital. The lesion was significantly more common, and occurred at a younger age in Negroes, and especially negro females. Hypertensive cardiovascular disease was verified in 99.5% of these patients. The locations, routes of rupture, length of survival and certain characteristics of the cerebrospinal fluid have been discussed.

Based on morphology, three types of cerebral hemorrhage — the hypertensive type, the hemorrhage into a preceding infarct, and an unclassified type — have been described, and their pathogenesis discussed.

WHAT'S YOUR DIAGNOSIS?

A 22-year-old white married female was admitted to the hospital on 24 February, 1965, complaining of vaginal bleeding and abdominal cramping of one week's duration. Her last menstrual period had begun on 11 January. She had completed two normal pregnancies three and six years previously. Examination revealed a small amount of bleeding from a bluish cervix. The uterus was enlarged to the size of a seven-weeks pregnancy and the urinary pregnancy test was positive. Hgb. was 10.4 gm%. The bleeding subsided and the patient was discharged a few days later with a diagnosis of threatened abortion. She resented her pregnant state and repeatedly requested medication to interrupt the pregnancy, but none was given.

She was readmitted to the hospital two weeks later, again complaining of abdominal cramping and vaginal bleeding, also of a sensation of pressure in the rectum. Her hemoglobin was 9.7 gm% and the pregnancy test was again positive. Pelvic examination revealed a mass in the cul-de-sac extending up into the abdomen and palpable in the suprapubic area. The uterus was firm and somewhat larger than a two months' gestation. A consultant agreed that there was a mass in the cul-de-sac and felt that this was cystic. He suggested that consideration be given to the diagnosis of adnexal neoplasm. Vaginal spotting continued and one week later the mass in the cul-de-sac was found to be laterally larger and now extended up almost to the level of the navel. On the following day laparotomy was performed.

Thyroid Carcinoma

THE PROTEAN manifestations and often unpredictable natural history of carcinoma of the thyroid are well recognized. Many features of this disease are unique in the field of neoplasia. The cancer may appear in childhood, grow slowly, and be present for many years without causing symptoms. Metastases may be widespread without occasioning overt disability. These metastases, after total thyroidectomy, are sometimes spontaneously stimulated to produce sufficient thyroxine to maintain the patient in a euthyroid or, rarely, hyperthyroid state. Under these circumstances, the tumor may demonstrate a marked avidity for I^{131} and therefore be susceptible to destruction when sufficient dosage of irradiation is delivered by this means. An appreciable number of these metastases are also responsive to the administration of thyroid hormone, presumably through suppression of the thyroid-stimulating-hormone of the pituitary.

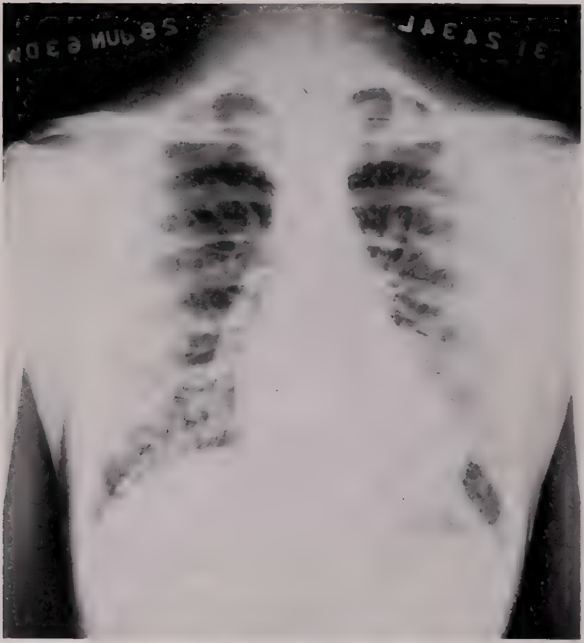

Fig. 1 — Roentgenogram of chest, June 1963. There are multiple irregular nodular densities throughout both lung fields, most numerous at the bases.

In some patients, problems are posed by the benign clinical appearance of the extensive pulmonary infiltration which encourages the diagnosis of sarcoidosis, fungal disease, or healed miliary tuberculosis rather than malignant infiltration. With the diagnosis established in the presence of spread of this degree, modification of the extent of neck dissection may be desirable and the optimal methods of treating residual tumor often rouse controversy. Furthermore, the true efficacy of the pattern of treatment finally selected may be extremely difficult to assess in

Unusual Clinical Features and Problems of Management

ALEXANDER J. WALT, M.D., F.A.C.S.
Detroit, Michigan

view of the unpredictable natural history of this disease. An unusual number of problems associated with this neoplasm were strikingly illustrated in the following patient.

Case Report

History

A married female, aged 24, was admitted to Detroit Receiving Hospital on October 30, 1959, for treatment of a Bartholin's abscess. On general examination it was noted that she had a nodular thyroid swelling estimated to weigh approximately 100 grams. The right lobe was larger than the left. On direct questioning, she thought that the gland had increased in size over the past year, but she had not experienced any pressure symptoms. A goiter had apparently been present for most of her adult life. There was no exophthalmos and she was clinically euthyroid. The pulse rate was 80, the blood pressure 100/60, and the circumference of the neck 32 inches. There was no history of irradiation to the neck in infancy or childhood and no history of goiter in her family.

Chest X-Ray Opacities

Radiographs of the chest revealed multiple discrete disseminated opacities (Fig. 1). It appeared that these had first been noted in 1950 when she was 15 years old (Figure 2). She had been referred at that time to Herman Kiefer Hospital, a tuberculosis center, following a routine x-ray of the chest. However, repeated examinations and many sputum tests failed to reveal any evidence of tuberculosis then or later. Her growth and development were normal, and serial radiographs of the chest revealed little change with time (Figure 3). In 1960, she was readmitted to Herman Kiefer Hospital for six weeks for further investigation. At this time a scalene node biopsy was performed which was reported as histologically normal.

Thyroid Growth

On June 25, 1963, the patient returned to the thyroid clinic at Detroit Receiving Hospital. She had recently experienced a slight amount of pain in the

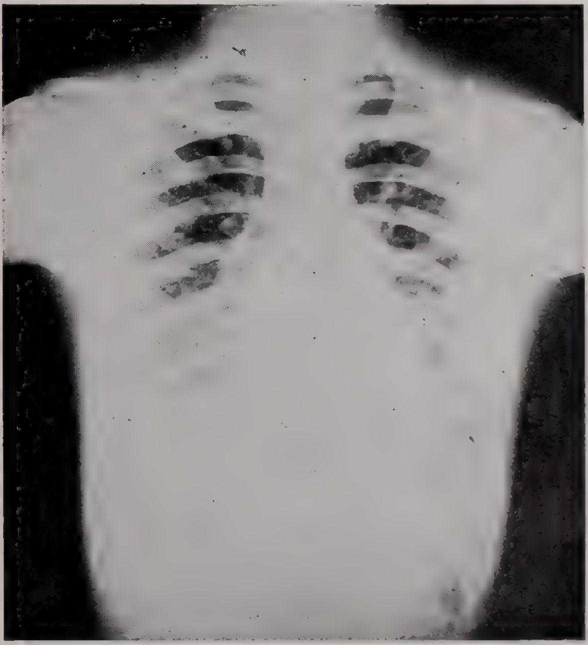

Fig. 2 — Roentgenogram of chest, January 1952. The multiple bilateral opacities in the lung fields show no change from a similar roentgenogram taken in 1950 when patient was aged 15.

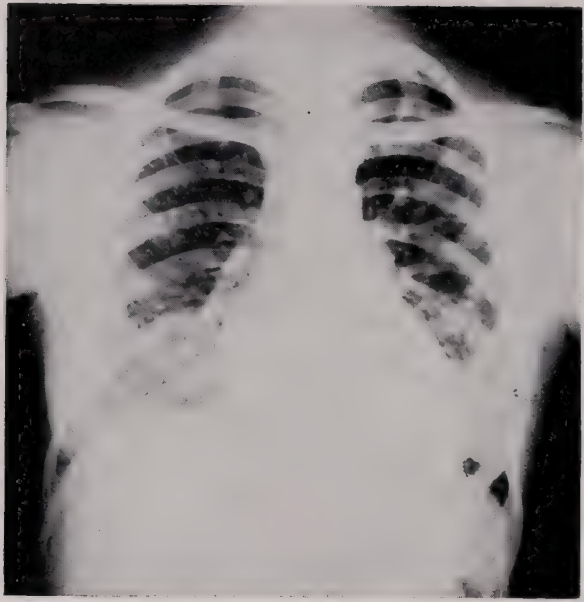

Fig. 3 — Roentgenogram of chest, October 1960. Very slight progression of the pulmonary lesions compared with films of 1952. Patient asymptomatic.

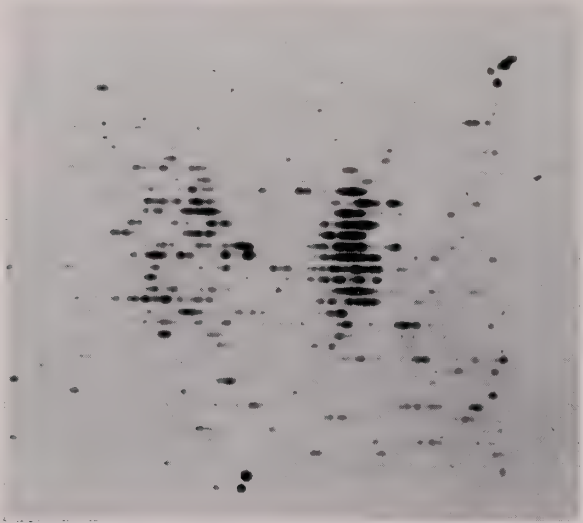

Fig. 4 — Preoperative scintiscan demonstrating irregular uptake in the thyroid gland with nonfunctioning areas, most marked over the isthmus.

region of the right lobe of the thyroid which she thought had become firmer and had grown larger over the preceding six months. She had lost ten pounds in weight earlier in the year but had recently regained this. There was no history of pressure symptoms, changes in voice, hair or skin, or any signs of hyper or hypo-thyroidism. On examination, the right lobe of thyroid was larger than the left and had caused slight deviation of the trachea towards the left side. The thyroid gland was firm and nodular, and a number of discrete lymph nodes were easily palpable laterally in the area of the middle and upper cervical chain, the largest node measuring about 1.8 centimeters. There was no lymphadenopathy palpable on the left side. The rest of the physical examination failed to reveal any abnormalities. The radiographs of the chest taken over the past decade were reviewed, and there appeared to be little change in the most recent film (Figure 1), which showed the same diffuse bilateral opacities that had been present since 1952. Skin tests for tuberculosis, coccidioidomycosis, and histoplasmosis were all negative. A barium swallow on 7/6/63 revealed deviation of the trachea and eosophagus to the left. A roentgenologic survey of the skeleton disclosed no abnormalities. The heart and upper mediastinum were within normal limits. The hemoglobin level was 10.9 grams per 100 ml. Preoperative scintiscan of the thyroid revealed irregular patchy uptake of I^{131} with large hypofunctioning areas (Figure 4).

Operative Procedure and Findings

Operation under general anesthesia was performed 7/10/63. Very early in the operation it became obvious that the strap muscles were firmly adherent to the underlying thyroid gland and that there was abnormal vascularity in the area. In view of this, the strap muscles were incised close to the sternomastoid muscles bilaterally so that these could be removed in continuity with the thyroid; and the largest lymph node, which had been easily palpable clinically, was excised. This measured approximately 2.5 centimeters and was sent for frozen section. Histologically the entire area consisted of thyroid follicles, and no lymphoid tissue could be demonstrated. As the mass was situated in the lateral area of the neck, however, and was separated by at least two inches from the thyroid gland, it seemed that this must be a metastatic lesion, and it was decided to proceed with the operation on this premise. A total thyroidectomy was performed, during the course of which the recurrent laryngeal nerves on both sides were exposed for a considerable distance. It was soon discovered that a chain of hard lymph nodes extended from the lower pole of the thyroid down into the superior mediastinum bilaterally. These nodes were freed from the recurrent laryngeal nerves but were inseparable from the lower parathyroid glands on both sides. They were therefore sacrificed with the specimen. Toward the end of the dissection of the thyroid gland from the trachea it was found that no plane of cleavage existed anteriorly and that it was necessary to excise a portion of the tracheal fascia and cartilage in order to remove the thyroid gland. It was obvious at this point that the deeper portion of the gland was replaced by a large solid tumor which had infiltrated through the posterior surface into the trachea and had actually penetrated through the wall of the trachea over a distance of approximately 3 x 3 millimeters. In addition to this, overt tumor tissue was attached to the trachea over an area of approximately 1.2 centimeters. This tissue was shaved off the trachea. With the thyroid removed, a finger could be inserted into the superior mediastinum. It was noted that a large involved mass of lymph nodes measuring approximately 6 x 5 centimeters was present in the area behind the manubrium. By careful dissection, this mass of metastatic lymph nodes was removed from the superior mediastinum.

The right and left upper parathyroid glands were identified and preserved, but it was noted that their vascular supply was precarious because of their close attachment to the involved lymph nodes and the surrounding inflammatory process.

With proven involvement of the trachea, extensive invasion of lymph nodes in the superior mediastinum, and the preoperative demonstration of presumably metastatic lesions throughout both lung fields, bilateral neck dissection was felt to be unnecessarily aggressive in these specific circumstances. Consequently, only the nodes immediately adjacent to the internal jugular veins were removed. In view of the penetration of the tumor into the trachea and the anticipated need to deliver heavy postoperative radiation in this area, a tracheostomy was established at the conclusion of the procedure.

Pathology

The gross specimen measured approximately 10 x 8 x 3.5 centimeters. The right lobe was larger than the left and the entire anterior surface was nodular (Figure 5). The central area of the gland, particularly over the region of the isthmus, was replaced by solid yellowish-tan colored tumor tissue which had completely replaced the posterior surface in the midline and had transgressed the thyroid capsule (Figure 6). The lymph nodes submitted varied in size from 2 x 2 millimeters to 2 x 2 centimeters and were tan-grey in color. Histologically the tumor showed features of a follicular adenocarcinoma with varying degrees of differentiation ranging from solid masses to well-differentiated follicles filled with colloid (Figure 7). Part of the capsule of the thyroid was infiltrated and involvement of the perichondrium of the trachea was noted in some of the sections (Figure 8). No papillary component was found in the multiple sections that were examined.

Progress

Postoperatively both vocal cords moved normally but the patient developed severe tetany 48 hours after surgery. The serum calcium fell to 5.2 milligrams percent. She was treated with intravenous calcium gluconate and was gradually brought under control with calcium lactate orally, amphogel, limited dairy products to reduce phosphorus absorption, and ultimately between 150,000 and 300,000 units of vitamin D daily. This tetany has remained permanently. In addition, the patient was initially given three

The density below this is due to the presence of a temporary tracheostomy tube.

grains of thyroid extract daily as hormonal replacement but soon developed symptoms suggestive of toxicity on this dosage, finally stabilizing on 1½ grains of thyroid extract daily.

Radioactive Iodine Studies

After she had recovered from the immediate effects of the operation, she received 17.5 millicuries of I^{131} purportedly for purposes of carrying out a complete body scan on 7/31/63. This scan (Figure 9) revealed metastatic nodes on both sides of the neck, a small area immediately above the tracheostomy tube and extensive bilateral pulmonary infiltration. After considerable discussion by members of the thyroid clinic of the optimal treatment but without final unanimity of opinion, it was decided to administer a therapeutic dose of I^{131} for the purpose of treating the area of tracheal involvement above the tracheostomy tube and to follow this with heavy irradiation of the same area. One hundred millicuries of I^{131} was given on 8/7/63 and was followed by 5,000 R of external irradiation to the area of the tracheal involvement between 8/22/63 and 10/25/63.

Follow-up

The patient continued to be followed through 1964. It was noted that no symptoms or signs of hypothyroidism developed when she was taken off thyroid extract for six weeks prior to a scintiscan for the purpose of delineating the residual metastases. The protein-bound iodine and butanol-extractable iodine at this point were 4.5 and 3.8 micrograms percent respectively. During this period of thyroid withdrawal she developed an accentuation of her tetany, and the vitamin D dosage was temporarily increased to 300,000 units daily with an increase in intake of calcium lactate orally. Under this regimen serum calcium has fluctuated between 8.2 and 10.4 milligrams with the phosphorus remaining at approximately 4.5 milligrams percent. Between 1/10/64 and 1/12/64, ten units of thyroid stimulating hormone was given daily, following which a scintiscan was carried out once again. No change in the metastases was observed and a bone survey was negative. On 2/5/64, 150 millicuries of I^{131} was given. Scintiscans on 2/28/64 and 5/29/64 performed after appropriate preliminary cessation of thyroid hormone revealed no significant change in the extent or distribution of the metastases except for disappearance of uptake over the tracheal area. On 12/17/64, pulmonary function tests were performed by Dr. B. Lewis to serve as a baseline for future observation. These revealed a moderate decrease of vital capacity and diffusing capacity without obstruction to air flow. The findings were as follows (anticipated normal in parentheses): Vital capacity 2,516 cc. (3,260); One-second vital capacity 1,914 cc. (2,930); Maximum expiratory velocity 237 L./Min. (400 L.); Maximum mid-expiratory flow rate 115.8 L./Min. (216 L.); Maximum breathing capacity 74.5 L./Min. (86 L.) 13.0 ml/mmHgxmin. (17.5).

When last seen in February 1965, the patient was taking two grains of thyroid extract, 10 grams of calcium lactate, and 200,000 units of vitamin D daily. She was in excellent condition and completely asymptomatic except that she is now three months pregnant with her sixth child. Radiographs of the chest showed regression of the pulmonary opacities (Figure 10).

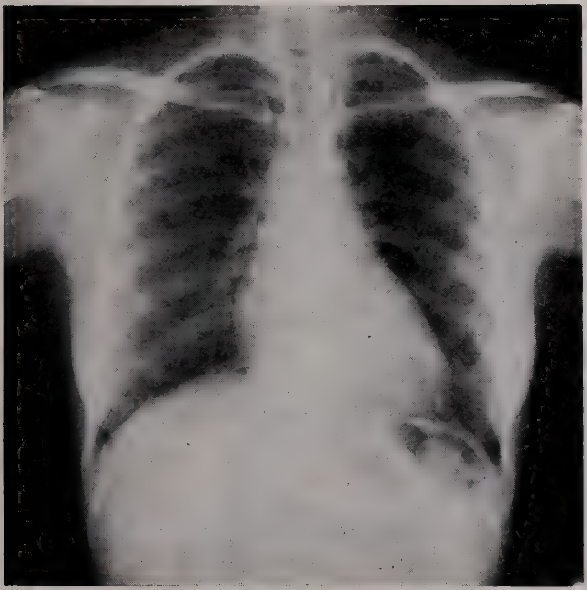

Fig. 10 — Roentgenogram of chest, February 1965. Marked regression in size and extent of pulmonary metastases.

Discussion

It has become well recognized over the past decade that carcinoma of the thyroid is an unusual but not rare malignancy of childhood and adolescence,[1] associated in a significant number of cases with prior irradiation of the neck or thymus. Some of these young patients have presented with widespread discrete pulmonary metastases which give rise to the so-called "snow flake" effect radiologically and yet have had few if any subjective symptoms. Some of these patients, like ours, are mistakenly diagnosed and treated as having tuberculosis or sarcoidosis on the basis of these radiological findings. Furthermore, this pathological picture is compatible with comfortable and perhaps asymptomatic survival for many years, especially if the tumor is responsive to hormonal influences and therefore susceptible to treatment with thyroid hormone as first described by Dunhill in 1937.[2] We have been able to document in this patient the fact that her pulmonary involvement was well established by the time she was 15 years old and that it had apparently progressed little in the 15 years that had since elapsed, despite the absence of any treatment. This makes the objective assessment of the results of treatment very difficult and stresses the need for long-term follow-up periods in thyroid malignancies.

Therapy

Therapy has posed some unusual problems and has involved many different modalities. The principle of surgical removal of as much of the primary lesion as possible was followed. It was recognized that the tracheal involvement was the area of greatest immediate hazard and that, although the obvious area of infiltration was excised, some residual involvement probably remained. This was later confirmed on I^{131} tracer studies. Administration of preoperative I^{131} and the use of a probe at the operating table to detect residual radioactivity as advocated by Dobyns may have been useful. The possibility of a partial tracheal resection with prosthetic replacement or major resection with the establishment of permanent tracheostomy was entertained but rejected in view of the known extensive pulmonary involvement. Results with the former have been unsatisfactory, and the latter procedure was considered to be unjustifiably mutilating. Instead, with the overt tumor excised, considerable reliance was placed on subsequent radiotherapy, both external and by I^{131}, in the hope that this would sterilize the small amount of residual neoplasm in this region. In view of her pregnancy, no recent scintiscan of this area is available. It should be noted, however, that absence of uptake of I^{131} in this region which has had heavy irradiation does not necessarily ensure absence of tumor. It is possible that neoplastic cells altered by irradiation remain viable but have merely lost the capacity to concentrate iodine.

In spite of the widespread involvement of both lungs, the patient has little impairment of her pulmonary function tests. Both pulmonary and lymph node metastases were demonstrated to have a marked affinity for I^{131}. It was therefore vital in determining therapy that considerable thought be given to the possibility that massive doses of I^{131} delivered to diffuse, receptive metastases of this magnitude might produce iatrogenic disability and subsequent death through the mechanism of radiation fibrosis, as has been documented by Rall et al.[3] Consequently, after administering 250 millicuries I^{131} without any immediate change, it was decided to avoid further doses unless the lesions showed significant progression. One year after the last dose, however, radiographs of the chest demonstrate regression of the metastatic lesions. Nevertheless, this benefit cannot be unequivocally ascribed to I^{131} therapy as she has been on thyroid hormone continuously since thyroidectomy and the regression may be due to hormonal suppression.

Pregnancy

Finally, the present pregnancy has also posed special problems. While there has been speculation in the past about the possible exacerbation of thyroid malignancy by pregnancy, there is no convincing evidence to support this concept. We are concerned, however, about the possibility of injury to the fetus from the large quantities of vitamin D on which the patient depends for control of her tetany and which may conceivably pass the placental barrier. If the fetus has a sustained iatrogenic hypercalcemia resulting from a high blood vitamin-D level, the possibility of the syndrome of supra-aortic valvular stenosis, mental retardation and facial changes occurring must be considered.[4] It was decided that there is not sufficient evidence at the present time to warrant termination of the pregnancy; but the effect on the fetus will be very carefully observed.

Summary

A female patient who had widespread bilateral pulmonary metastases from adenocarcinoma of the thyroid at the age of 15 remained asymptomatic and untreated until the age of 28 when she presented with an enlarging goiter. Despite total thyroidectomy and removal of many involved lymph nodes, she has sufficient residual functional tissue to maintain a state of euthyroidism. Although she still has widespread metastatic involvement both in the neck and in the lungs, she remains in excellent health.

MALIGNANT ARGENTAFFINOMAS of the bowel or lung when associated with liver metastases may give rise to the carcinoid syndrome.[1] About one half of these patients exhibit certain cardiovascular changes attributed to the pharmacological properties of serotonin or 5 hydroxy-tryptamine.[2,3] Recent work suggests that the protean clinical manifestations may be due to other vasoactive agents in addition to serotonin. Histamine and other active analogues of serotonin have been detected in significant amounts in the circulating blood of these patients.[4,5] Robertson and his co-workers[6] were able to produce flushing in patients with the carcinoid syndrome by the intravenous administration of epinephrine, and on the basis of their experiments, questioned that serotonin is the agent mediating the flush. In an attempt to elucidate the effects of serotonin on the cardiovascular system and to search for other circulatory substances that may be contributory, we have studied the circulatory hemodynamics and measured the blood histamine and catecholamines** as well as serotonin levels in a recent patient with the carcinoid syndrome.

Case Report

A 60-year-old white male was admitted to the Dearborn Veterans Administration Hospital for the first time on February 2, 1964. His symptoms had begun insidiously approximately two years prior to admission. He complained primarily of persistent diarrhea and episodes of facial flushing and sweating, associated with weakness, abdominal cramps and diarrhea, and a sensation of persistent fullness in the epigastrium which seemed to be getting worse over the two-year period. He had a poor appetite, felt that he was becoming progressively weaker, and had noted a weight loss from 220 to 182 pounds. He denied any paroxysms of breathlessness associated with these episodes. However, he had experienced some exertional dyspnea which had been getting worse in the few months prior to his admission, when it was associated with some swelling of the ankles. He had been admitted to another hospital on January 25, 1964, where an exploratory laparotomy was performed and an 8 x 10 cm. mass in the left lobe of the liver was biopsied. There were also two metastatic nodules in the right lobe. He was then transferred to this hospital.

Physical Findings

On the initial physical examination his blood pressure was 198/100. There was noted a reddish malar flush, and the patient appeared to be sweating excessively. The neck veins were not distended. The anteroposterior diameter of the chest was increased disproportionately for the patient's age. The maximal intensity of the heart beat was felt 2 cm. to the left of the midclavicular line. There was a Grade III/VI systolic murmur along the left sternal border between the second and fourth intercostal spaces. The rhythm was regular; the rate, 80. The abdomen was visibly distended in the epigastrium and left upper quadrant. There was a firm mass about 8 x 10 cm., which was thought to be in the left lobe of the liver, whose edge could be palpated 7 cm. below the xiphoid and 12 cm. below the right costal margin. The edge of the spleen was palpable just below the left costal margin. There was a 2+ pitting pretibial edema and telangiectases noted over the face and the upper part of the trunk.

**See Test Your Word Score Page 97.

Laboratory Findings

The hemoglobin was 16 grams; hematocrit, 45%; alkaline phosphatase, 7 Bodansky units; total serum protein, 6.8 gm.% with a globulin of 1.4 gm.% and an albumin of 4.7 gm.%. The total serum bilirubin was 1.8 mg.% with a direct bilirubin of 0.9 mg.%. The transaminase was 22 units. The urine was positive for 5 hydroxy-indole-acetic acid with the nitroso-naphthol reagent.[7] An electrocardiogram showed left ventricular hypertrophy. A chest x-ray revealed cardiomegaly, pulmonary congestion, and changes compatible with pulmonary emphysema. An upper gastrointestinal series, a barium enema, and an intravenous pyelogram were all normal.

The patient's hospital course was characterized by refractory congestive heart failure and progressive hepatosplenomegaly. He was noted to have episodes of sweating and facial flushing and persistent diarrhea. His blood pressure ranged from 115/90 to 198/100, but hypertension could not be correlated with the above episodes, nor could pressure on the tumor mass elicit such an episode.

Biopsy

The liver biopsy showed the parenchyma to be compressed and displaced by poorly circumscribed nests and sheets of small cells with the alveolar pattern of carcinoid type of adenocarcinoma (Figure 1). Dilated and congested anastomotic venous channels surrounded and apparently lined by tumor cells were a striking feature in many areas (Figure 2). A few small glands, some of which contained inspissated amorphous eosinophilic material in the lumens, were present in other less well differentiated areas of the tumor.

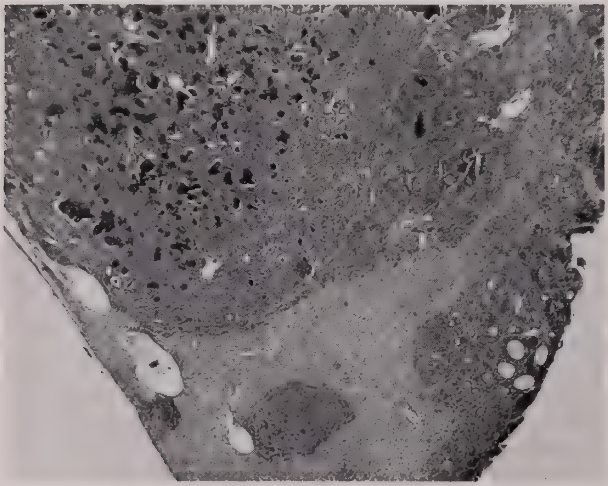

Fig. 1 — Wedge biopsy of liver which is infiltrated by metastatic carcinoid tumor. H&E x 6.5.

Arteriogram

Right heart cardiac catheterization and a pulmonary arteriogram were performed, at which time hepatic vein, peripheral artery, and vein blood samples were drawn for determination of serotonin, catecholamines, and histamine. He did not experience any flushing during catheterization. The results of the cardiac catheterization are presented in Table 1, and the blood determinations in Table 2. Simultaneous pulmonary artery and right ventricular pressure tracings are shown in Figure 3 and a pulmonary arteriogram in Figure 4.

The patient was treated with digitalis, cyproheptadine hydrochloride (Periactin), and hepatic artery infusion of 5 fluoro uracil. His progress was complicated by occurrence of an acute myocardial infarction from which he has recovered. He remains alive, but his course is compatible with progressive tumor growth.

Methods

Blood gases were measured by the method of Van Slyke, and cardiac output was determined by the Fick method.

The protocol for the measurement of serotonin was as follows: 0.5 ml. of blood was pipetted into a 40 ml. glass-stoppered centrifuge tube, followed by 0.5 ml. of distilled water, 1 ml. of ascorbic acid — edathamil reagent (300 mg.% ascorbic acid in 1% edathamil disodium salt), 1 gm. of sodium chloride, 3 ml. of 0.1 M borate buffer pH 10 and 7 ml. of butanol. The contents were mixed by gentle swirling for 10 minutes and then centrifuged at 2000 r.p.m. for 15 minutes. Five ml. of the butanol layer was then introduced into another glass-stoppered centrifuge

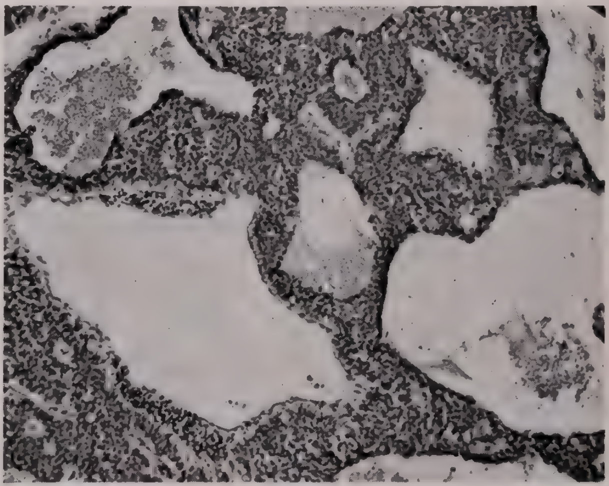

Fig. 2 — Portion of metastatic carcinoid which contains venous "lakes." H&E x 65.

tube containing 7 ml. of heptane and 5 ml. of 0.1 N Hcl. The contents were mixed thoroughly and centrifuged. Three ml. of the hydrochloric-acid extract was pipetted into a quartz cuvette (Turner No. 110-802) and 1 ml. of concentrated Hcl was then added to it and mixed. The fluorescence was then measured in a Turner fluorometer equipped with Far Ultra Violet Lamp (Turner No. 110-851). The primary filter used was a combination of Corning No.'s 7-54 and 0-53 (297 mu) and the secondary filter was a Corning No. 2A-12 (350 mu). The concentration of serotonin in the sample was determined by comparing its fluorescence with a serotonin standard.

Histamine was determined following the method described by Shore.[8] Total catecholamines were determined by the method of Price and Price.[9]

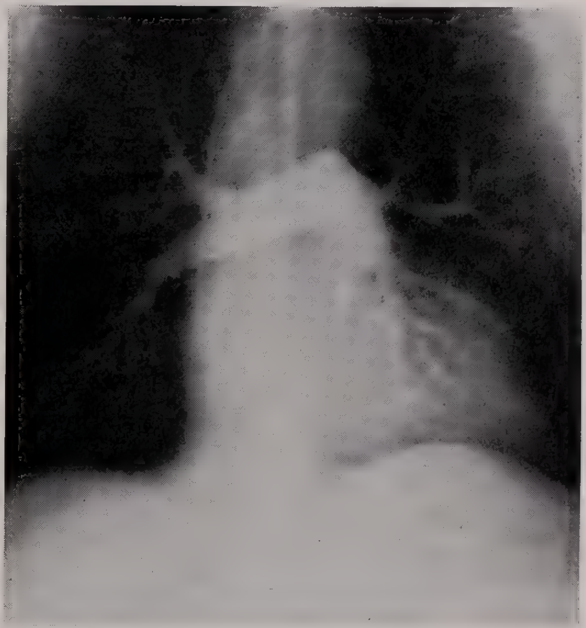

Fig. 4 — Pulmonary arteriogram.

Discussion

McKusick[10] has reserved the term "carcinoid syndrome" for those patients who exhibit cardiovascular changes. The lesions in the heart are chronic endocarditis and valvulitis, which are quite distinct histologically from those produced by rheumatic fever. These changes are observed primarily on the right side of the heart affecting the pulmonary and tricuspid valves, frequently resulting in functional stenosis or regurgitation. The nearly complete preponderance of these lesions on the right side of the heart has been explained by the inactivation of serotonin as it circulates through the lungs. Goble,[11] by sampling blood from the pulmonary and the brachial arteries simultaneously, found that two thirds of the serotonin in the pulmonary artery is removed from the blood during passage through the lungs, presumably by a monoamine oxidase in the lung, which converts 5 hydroxy-tryptamine to 5 hydroxyindoleacetic acid, a pharmacologically inactive degradation product. However, Sjoerdsma[3] has measured serotonin levels in pulmonary artery, antecubital vein, right atrium, and femoral artery, and was able to detect no significant differences. The left side of the heart has been involved, and mitral and aortic lesions have been found in patients with patent foramen ovale with some right to left shunting of blood.[10,12] Recently a case has been reported[13] of carcinoid heart disease with left-sided endocardial and valvular lesions found at post-mortem examination, with a closed foramen ovale and no lung metastases. This patient also had right-sided heart lesions which were much more severe than those found on the left side.

Increased Pulmonary Pressure

The prominent feature of the catheterization data in our patient was the markedly elevated pulmonary artery pressure and increased pulmonary arteriolar resistance. The pulmonary wedge pressure, an indirect measurement of left atrial pressure, was within normal limits, which would indicate that pulmonary arteriolar constriction or obstruction, rather than pulmonary venous constriction, was responsible for the elevated pulmonary artery pressure. The elevated right ventricular pressures and right atrial pressures were a reflection of some degree of right heart failure, probably secondary to the increased pulmonary resistance. This patient clinically was not in left heart failure at the time of the study; however, there were previous clinical indications of associated left heart failure. He had systemic hypertension and associated changes of left ventricular hypertrophy by x-ray and by electrocardiogram. As he subsequently suffered an acute myocardial infarction, it is presumed that he had arteriosclerotic heart disease. Thrombosis is a prominent feature of the carcinoid syndrome; and when it occurs in the lung, it may be partially responsible for the elevated pulmonary artery pressure. Occlusion of small parenchymal arteries of the heart by thrombosis resulting in myocardial infarction without occlusion of the major coronary vessels has been demonstrated.[10] The cardiac index in this patient was low and could be a result of the obstruction of the pulmonary arteriolar bed or a reflection of disease of the left side of the heart. Low cardiac output in the carcinoid syndrome has been reported by Wood[14] and Schweizer.[13] To our knowledge an increased cardiac output has never been reported in the carcinoid syndrome. There was no indication in this patient of valvulitis, either stenosis or regurgitation. Simultaneous pulmonary artery and right ventricular pressure tracings showed no systolic gradient across the pulmonary valve, and there was no evidence of tricuspid stenosis from the right ventricular diastolic and right atrial pressure tracings. Injection of dye into the pulmonary artery revealed no regurgitation through the pulmonary valve.

TABLE 1
Cardiac Catheterization Data

	Rest	Exercise
Pulmonary wedge pressure: mm Hg	(10)	
Pulmonary artery pressure	55/18 (25)	62/22 (53)
Right ventricular pressure	55/0-10	62/5-12
Right atrial pressure	(10)	
Hepatic wedge pressure	(10)	
Hepatic vein pressure	(10)	
Cardiac rate	84	105
Cardiac index: L/min/M^2	2.1	2.3

TABLE 2
Histamine, Serotonin and Catecholamine Levels
(Micrograms Per Liter of Blood)

Type of Blood	Histamine	Serotonin	Total Catecholamines
Arterial blood	121	360	1.36
Hepatic vein blood	113	350	0.34
Peripheral vein blood	110	321	2.04
Normal values	40-100	90-180	0.1-0.85

Serotonin Level

In our patient the serotonin level was increased in the hepatic vein, in a peripheral arm vein, and in arterial blood. This is in agreement with previous studies by Sjoerdsma,[3] and by Pernow and Waldenstrom.[4] Peart and his group[5] could demonstrate no rise in serotinin in serial blood samples from a catheter in the hepatic vein during a flushing attack induced by intravenous epinephrine. The approximately equal serotonin levels in the hepatic vein, the peripheral arm vein, and the arterial blood indicate a steady release of serotonin from the tumor; and the absence of any significant rise in serotonin in hepatic vein blood during an episode of flushing casts doubt on the etiological role of serotonin in precipitating the flush, and perhaps in other vasomotor phenomena observed in the carcinoid syndrome. The lack of any detectable difference between the venous and arterial concentrations of serotonin indicates that there was probably no significant inactivation of serotonin in the pulmonary vascular tree.

Histamine

We also found elevated and approximately equal histamine concentrations in the hepatic vein, peripheral vein, and arterial blood. It has been postulated by Waldenstrom[15] that serotonin triggers the release of histamine, and it is the histamine which is responsible for some of the manifestations of the carcinoid syndrome, such as flushing and sweating. Whether histamine is secreted by the tumor cells in the liver, or whether histamine release from the liver and other sites is stimulated by serotonin,[16] or whether the increased activity of a decarboxylase enzyme in converting 5 hydroxy-tryptophane to serotonin may also decarboxylate histadine to histamine as well,[15] the result would be the same: increased histamine blood levels, approximately equal in hepatic vein, peripheral vein and arterial blood, as observed in our patient. However, some investigators[17] have found normal histamine levels in blood and urine in the presence of elevated serotonin levels.

Rosenberg and his group[18] have reported the close relationship and interaction between endogenous circulating epinephrine, norepinephrine, and serotonin in producing the vasomotor changes associated with hemorrhagic and endotoxin shock. This relationship has also been demonstrated in anaphylactic shock.[19] It has been repeatedly shown that exogenous epinephrine or norepinephrine can produce a typical flush in the carcinoid syndrome.[5,20] This work raises the interesting question of the possible role of the catecholamines in the carcinoid syndrome. The level of catecholamines in the hepatic vein in our patient was normal; however, there was significant elevation of the catecholamines in the peripheral vein and in arterial blood. This would indicate that the catecholamines were not being liberated by hepatic metastases, but probably by the adrenal medulla. Whether this release is triggered by serotonin is uncertain. However, our patient did have increased catecholamine activity in the peripheral blood, and it is quite possible that interaction or balancing of concentrations of these endogenous circulating vasoactive substances results in blood pressure fluctuations and episodic flushing and sweating.

Summary

This patient with a histologically proven diagnosis of carcinoid tumor of the liver, exhibited some of the typical cardiovascular changes: increased pulmonary artery pressure and pulmonary arteriolar resistance with a normal pulmonary wedge pressure. The serotonin levels in the hepatic vein, in a peripheral arm vein, and in arterial blood were all abnormally high, and approximately equal. We also found abnormally elevated serum histamine levels in hepatic vein, peripheral vein, and arterial blood. The catecholamine levels were elevated in the peripheral vein and in arterial blood but were not increased in the hepatic vein. This would indicate that there are other vasoactive substances present in the circulating blood of the carcinoid syndrome besides serotonin, which may play a role in the manifestations of this disease.

Fear not that thy life shall come to an end, but rather fear that it shall never have a beginning. — Cardinal Newman

IT'S THE LAW

Association of Doctors Treated as Corporation for Income Tax Purposes

An association of doctors operating a clinic under articles of association similar to those used by corporations should be treated, for federal income tax purposes, as a corporation rather than a partnership, although state law prohibits the formation of corporations for the practice of medicine and most of the association's income came from personal services, a federal trial court ruled.

In June, 1960, two doctors who had operated a clinic as a partnership for a number of years formed an association to operate it. The articles of association, similar in form and substance to those used by corporations, vested management in a Board of Governors.

The association took over the assets and liabilities of the partnership, and all employees of the partnership became employees of the association.

The Board of Governors held regular weekly meetings of a corporate board of directors. All payments for medical services were placed in the association's bank account. Social Security Tax and income tax were withheld from the pay of all employees, including the doctors, and the required reports were filed with the government.

The government took the position that, for federal income tax purposes, the association should be treated as a partnership instead of as a corporation. In determining whether an organization qualifies as an association taxable as a corporation, the corporate characteristics of centralized management, continuity of life, transferability of interests, and limited liability must be considered. The association satisfied the first three criteria, the court said. No association could satisfy the fourth.

The fact that state law forbids the formation of corporations for the practice of medicine was not grounds for denying the association the status of a corporation for tax purposes, the court said.

Foreman v. U. S., 232 F. Supp. 134 (D.C., Fla., April 2, 1964) — Citation Vol. 10, No.4.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 31)

At surgery the pelvis was found to be filled with a large retroperitoneal hematoma containing one liter of blood. The hematoma rose within the right broad ligament, filled the retroperitoneal pelvic area and apparently destroyed the right tube, because this was not identified. The left tube and ovary and the right ovary were normal. In spite of entertaining a strong suspicion of vaginal instrumentation, no evidence of trauma could be found in the region of the cervix or vaginal vault. The uterus was slightly enlarged but otherwise normal. The pathologist reported a large amount of clotted blood, but also described a fallopian tube with chorionic villi and chronic salpingitis. Final diagnosis was ruptured right tubal pregnancy with an extensive pelvic retroperitoneal hematoma involving the right broad ligament.

Finish every day and be done with it. You have done what you could. Some blunders and absurdities no doubt crept in; forget them as soon as you can.

— Emerson

Patch-Grafting of the Gastrointestinal and Urinary Tracts*

A. P. THAL, M.D.**
R. SUKHNANDAN, M.D.**
A. ARBULU, M.D.**
T. HATAFUKU, M.D.**
Detroit, Michigan

THE FINDING that a defect in the gastrointestinal tract may be patch-grafted with the seromuscular surface of an adjacent loop of bowel allows the surgeon to widen a narrowed area or bridge a defect. Experimentally this approach has been used successfully in closing large defects of the distal esophagus[1] and the duodenum,[2] and in reconstruction of the esophagogastric junction,[3] the urinary bladder[4] and the ureteropelvic junction.[5] Clinically the method has shown promise in the management of spontaneous perforation of the esophagus[6] and of acid peptic stricture of the distal esophagus, and also in achalasia.[7]

Development of the Technique

The concept of patch-grafting arose from the difficulties encountered in managing injuries of the lateral wall of the second portion of the duodenum. After the wound edges were debrided, there was a lack of tissue for adequate closure. A similar problem was encountered when the lateral wall of the duodeum was involved by a right-sided hypernephroma or carcinoma of the hepatic flexure of the colon. It seemed that the application of the serosal surface of an adjacent loop of bowel might bridge the defect and that the resulting shallow ulcer formed by this reconstruction might in time be covered by an ingrowth of adjacent bowel mucosa. Experimental studies, using the duodenum as a model,[4] proved this hypothesis to be correct (Figure 1). In all areas of the bowel where it has been tried, with the important exceptions of the stomach and first portion of the duodenum, healing of these patch-grafts

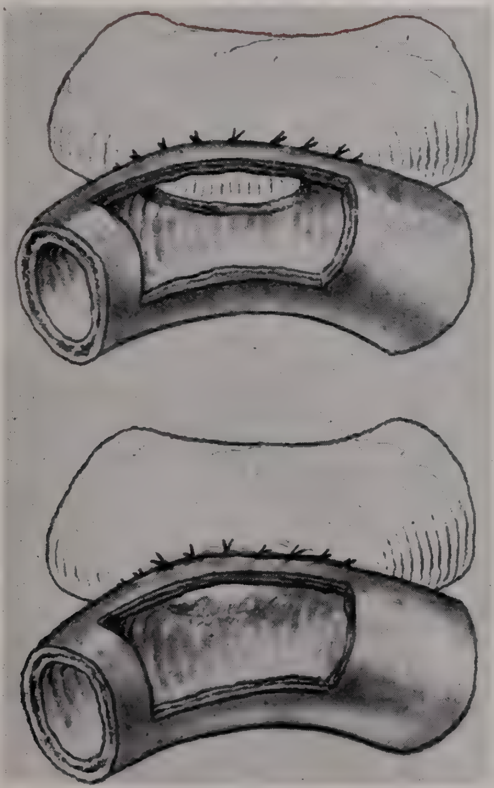

Fig. 1 — Application of patch over duodenal defect showing the ingrowth of duodenal epithelium over the surface of the adjacent loop of bowel.

takes place initially by the formation of granulation tissue on the seromuscular surface of the patch, followed by rapid growth of low cuboidal epithelium in the intestine and by flattened squamous epithelium in the esophagus. After eight weeks the duodenal patch is covered by a well-developed surface layer of duodenal mucosa showing a villous structure quite comparable to that in the adjacent duodenum.

Patch-Grafting of the Distal Esophagus and Esophagogastric Junction

Among the nonmalignant problems involving the distal esophagus, spontaneous perforation and stricture continue to challenge the surgeon. In our experience with the Boerhaave syndrome, patients who are also alcoholics often reach the hospital many hours or days after the perforation has occurred. At the time of exploration, there is mediastinal abscess and empyema; the edges of the perforation are hemorrhagic and necrotic. Our previous experiences in attempting primary closure of this form of advanced perforation has been uniformly unsuccessful. After application of a patch-graft of the stomach fundus drawn through an incision in the diaphragm, we have had primary healing in patients who have experienced perforation between 24 and 48 hours prior to operation. The operation is simply performed through a left lateral thoracotomy and is combined with vagotomy, gastric drainage procedure and gastrostomy (Figure 2).

A similar technique has been used in the treatment of distal esophageal stricture. By making an incision in the long axis of the stricture the problem becomes one of coverage of an anterior wall defect. After dividing the vasa brevia the fundus is mobilized and sutured over the anterolateral walls of the esophagus. In this way the normal caliber of the esophagus is restored and at the same time a flap valve is formed at the esophagogastric junction. The serosal surface of the stomach now facing into the esophageal lumen comes to be lined with squamous epithelium. In Figure 3 the application of the gastric fundus is depicted. Not only does it afford maximal widening of the esophagogastric junction but, by forming a double fold of fundus, a long valve-like entry of the esophagus into the stomach is secured, thus protecting against reflux esophagitis.

The Use of the Patch-Graft as an Experimental Gastric or Duodenal Ulcer Preparation

Hitherto, attempts to create gastric and duodenal ulcers operatively resulted in spontaneous and rapid healing. The use of the

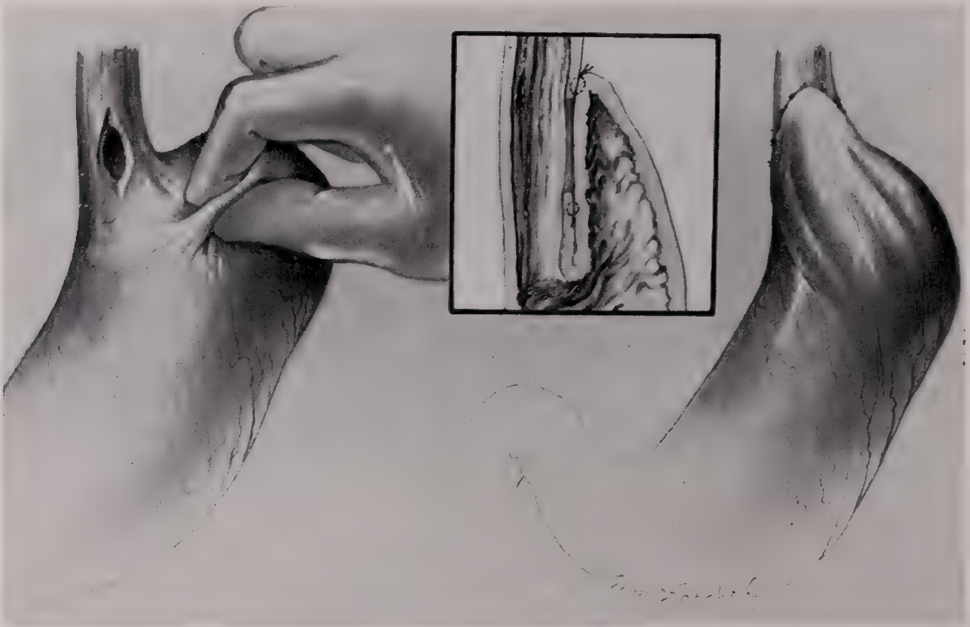

Fig. 2 — Patch-grafting of spontaneous perforation of the esophagus.

patch procedure to attain this objective was suggested by the finding that in the stomach and first portion of the duodenum healing of the patch failed to occur in over 70 per cent of animals; persistent ulceration and ultimately perforation of the patch into the bowel loop often developed. The experimental preparation is illustrated in Figure 4. A standard full-thickness defect, usually 2 cm. in diameter, is created with a cork borer in the dependent portion of the body of the stomach or first portion of the duodenum. Then an adjacent loop of bowel is sutured circumferentially, thereby creating a full-thickness ulcer. Control studies revealed that approximately 60 to 70 per cent of animals with this experimental ulcer have either persistent ulcer or fistula six weeks after operation, and when these animals are stimulated with histamine in beeswax the fistula rate is approximately 100 per cent. When meas-

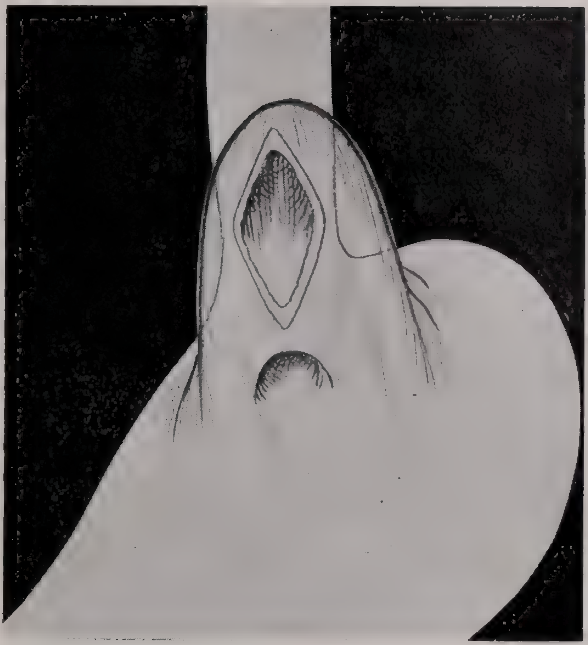

Fig. 3 — Fundic patch reconstruction of esophageal stricture.

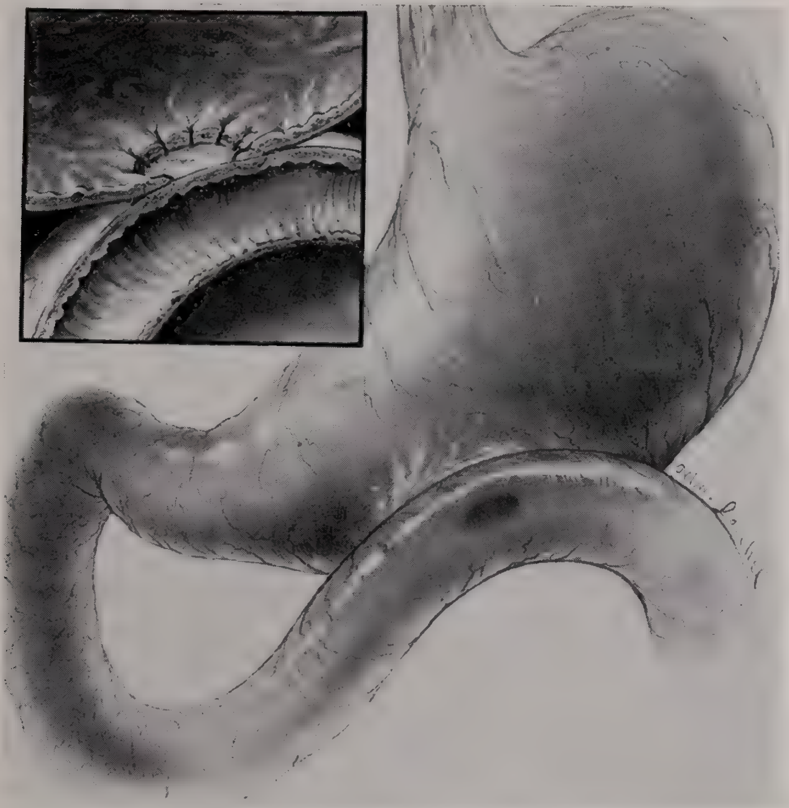

Fig. 4 — Experimental gastric ulcer preparation. A full-thickness defect is created in the stomach and patched with the seromuscular layer of an adjacent loop of bowel. Approximately 70 per cent of these persist as chronic gastric ulcers or form a fistula with the loop. When the preparation is stimulated with histamine, persistent gastric ulcer develops in all. The same preparation can be created in the first portion of the duodenum as an experimental duodenal ulcer.

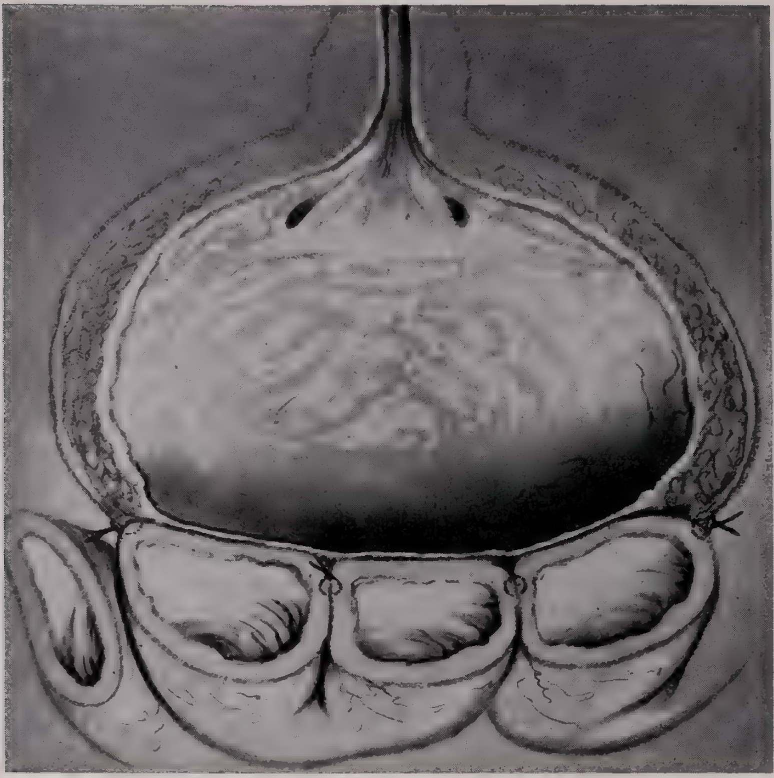

Fig. 5 — Bladder defect sealed by application of several loops of small bowel. Growth of bladder mucosa occurs across the seromuscular layer of the small bowel.

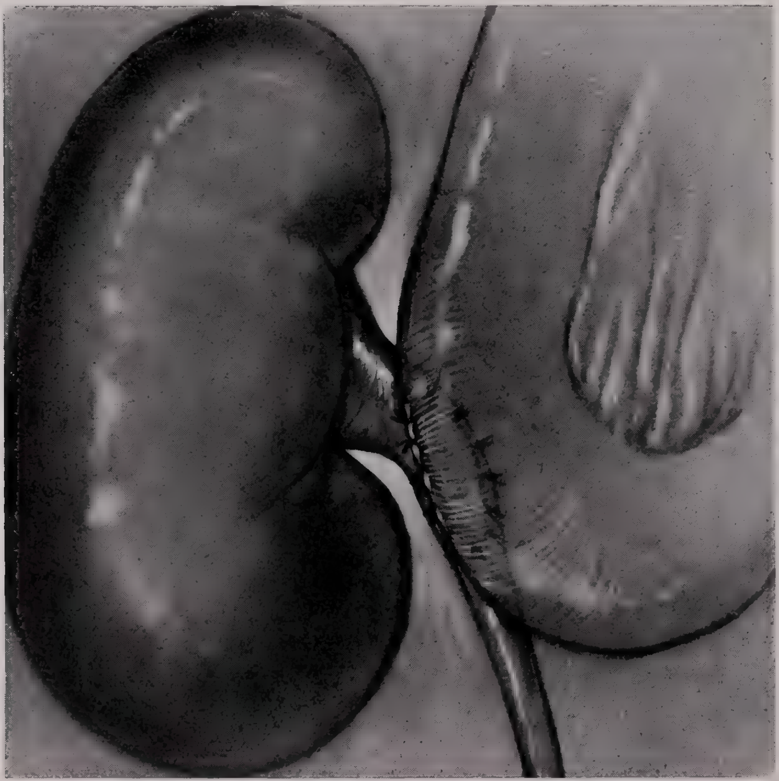

Fig. 6 — Defect in the ureteropelvic junction is patched by the application of an adjacent loop of duodenum.

ures are taken to ablate acid production, healing is rapid and uniform. The preparation appears to be of value in studying any procedure designed to suppress parietal cell activity in the intact stomach. It may be used to study the effect of anticholinergic drugs, of vagotomy, or of gastric freezing or radiation. After vagotomy, for example, approximately 90 per cent of experimental ulcers are healed and relined by gastric or duodenal mucosa within six weeks.

The Use of the Patch-Graft in the Urinary Tract

In the genitourinary tract problems may arise in regard to wide excision of a bladder tumor leaving a small residual urinary pouch, or with strictures occurring at the ureteropelvic junction. To both these problems the use of gastrointestinal patch-grafting may offer a solution worthy of clinical trial (Figures 5 and 6). Considerable enlargement of the dog urinary bladder can be secured by the use of three loops of small intestine plicated together in Noble fashion and applied directly over the defect with running catgut sutures. This enlarges the bladder, and regeneration of transitional epithelium occurs readily across the surface, enlarging the bladder without encroaching on the lumen of the bowel. Whether or not electrolyte and water absorption occurs across the intestinal patch applied to the bladder has yet to be studied.

Finally, the ureteropelvic junction may be enlarged by incision in the long axis followed by application of a conveniently situated loop of bowel as a patch-graft. In the human and in the dog, the second portion of the duodenum suffices well for reconstruction of the right ureteropelvic junction.

Summary

A method of patch-grafting defective or stenotic areas of the gastrointestinal and urinary tracts is described. The defect which is already present or which is created by incision through an area of stenosis is reconstructed by insertion of a patch of adjacent bowel wall. The seromuscular surface of this patch now facing into the lumen comes to be lined by mucous membrane native to the area.

Vanity is the death of good living. — Balzac

Pulmonary Surgery

Certain patients with pulmonary emphysema develop cystic spaces which are anatomically located immediately beneath the visceral pleura.[6] On occasion the entire hemithorax seems to be filled by giant nonfunctional air cysts, while the remaining lung is compressed and becomes atelectatic. (Figure 1). We would like to re-emphasize that patients with this type of pulmonary pathology can be said to have "surgical emphysema"; for one can expect functional improvement with a properly planned and executed surgical procedure.[4,5,7,8]

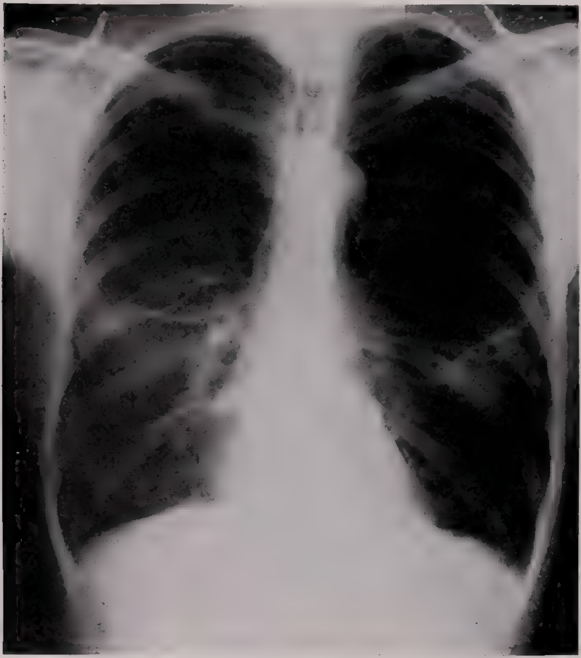

Fig. 1 — Bilateral space-occupying air cysts resulting in vanishing lung fields in the upper lobe areas. This location is typical in patients with giant bullous emphysema.

The Nature of the Patient

During the last eight years, 23 male patients with bullous emphysema have had 27 surgical procedures performed for this condition at the Dearborn Veterans Hospital. Their average age was 41 years, the range being 32-55. One patient had been treated for clinical asthma.

Excessive Smoking

All smoked more than one pack of cigarettes per day. Timed vital capacity and maximum breathing-capacity determinations were obtained before the operative procedure and serially postoperatively when possible.

Pulmonary Distress

The reason for hospital admission is given in Table 1. Only four patients had no pulmonary symptoms. Three were admitted because abnormality of the chest roentgenogram was noted. The patient with pancreatitis had no symptoms referable to his chest but was found to have a fluid-filled pulmonary cyst from which the tubercle bacillus was later recovered. In addition to the eight patients that were admitted with pneumothorax, four others had a previous history of this complication. It is interesting that dur-

ERNEST M. BERKAS, M.D.**
Dearborn, Michigan

ing this eight-year period only four patients have been operated upon for respiratory insufficiency alone.

Tuberculosis Cysts

Five patients had fluid-filled cysts and two were found to have tubercle bacilli as the cause of the fluid. Another patient, treated preoperatively with streptomycin, had the histologic appearance of tuberculosis, but acid-fast bacilli were not cultured from the specimen. A typical case is seen in Figure 4 with multiple fluid levels. A previous chest x-ray taken one year earlier demonstrated the air spaces without the fluid.

There was no operative or late mortality and there were no serious complications in the 23 patients.

Procedures

Cystectomy and Obliteration of the Pleural Space

In 17 operations on 15 patients the surgical procedure was limited to a wedge resection of the blebs or simply unroofing the air sacs and ligating the bronchial communications. The remaining functional lung parenchyma was re-expanded to fill the hemithorax. The pleural space was obliterated by gauze abrasion of the pleura or by partial parietal pleurectomy.

It was found that patients with the poorest pulmonary function derived the most benefit from the surgical procedure. If the vital capacity was less than 75% of the predicted value, improvement was routine. The excep-

tions were the oldest patient, #8, and the patient with asthma, #9. Of the six patients whose pulmonary functions were greater than 75% of the predicted, only one had significant improvement after resection of emphysematous blebs.

There has been to date no recurrence of pneumothorax or x-ray evidence of giant air-cyst recurrence.

Segmentectomy and Lobectomy

It was thought best by the operating surgeon to remove a segment or a lobe in nine patients (10 operations). Figure 2 demonstrates the resected right upper lobe of patient #23. Figure 3 shows the apical and posterior segments of the right upper lobe in patient #16. It can be seen that a portion of the lobe and segments deflate while the cysts remain inflated. The deflated lung had functional potential, and it was noted that whenever segmental resection or lobectomy was done, potentially functional lung tissue was removed as well as cystic lung.

Table 3 demonstrates that pulmonary

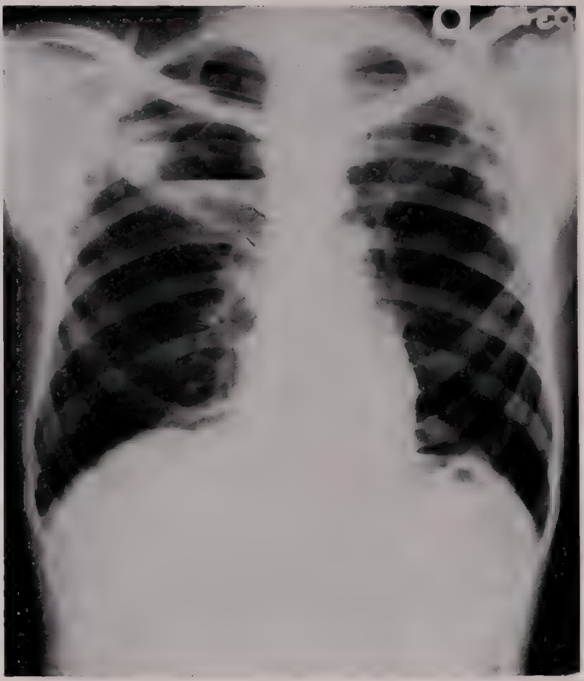

Fig. 4 — Air-fluid levels in patient #13 who was admitted with pancreatitis. A previous x-ray had demonstrated bullous emphysema in the right upper lobe area. Smear and culture of the fluid removed at surgery was positive for tubercle bacilli.

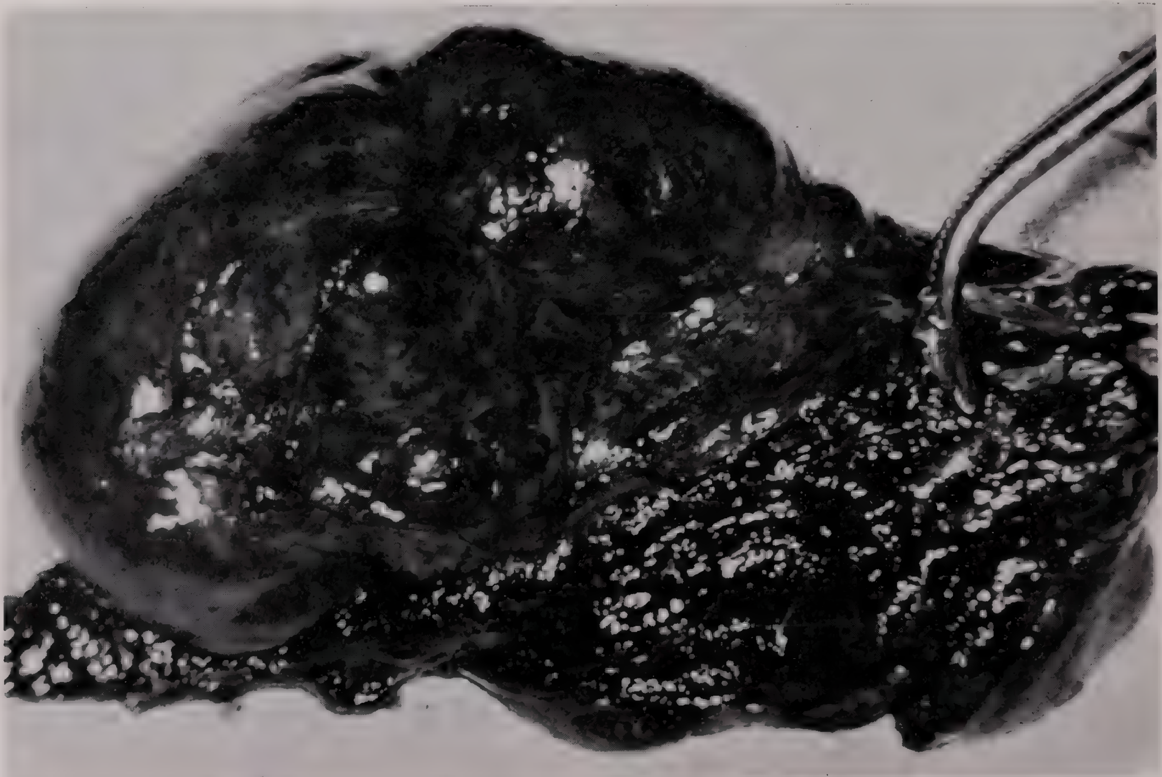

Fig. 3 — Apical and posterior segments of the right upper lobe of patient #16, which are atelectatic while gas remains trapped in the surface cyst.

function did not necessarily improve after segmental resection or lobectomy, although all patients except #16 had preoperative pulmonary functions of 75% or more than predicted.

Discussion

Bullous emphysema has been termed the "vanishing lung" syndrome[1] inasmuch as the natural history of an acquired air cyst is one of expansion. Because gas flow is into the cyst alone, it has been noted to expand on coughing and expiration.[4] As the cyst grows, the functional parenchyma vanishes as it becomes compressed and atelectatic.

Although a pathologic distinction is made

Pre and postoperative pulmonary functions in patients who had segmentectomy or lobectomy to remove their air spaces.

between bullae and giant blebs,[6] they both cause the same symptoms and secondary complications, and are therefore clinically indistinguishable. For practical purposes one can consider both bullae and blebs as acquired lung cysts.

The etiology of these cysts is unknown, although they appear to be associated with partial expiratory obstruction. Many of these patients have asthma, chronic bronchitis and generalized pulmonary emphysema. However, the average age of these patients is younger than that of symptomatic generalized emphysema.[7]

The symptoms and secondary complications of these cysts are due to the mechanics of a space-occupying mass. If the visceral pleura overlying a cyst ruptures, air leaks into the pleural space resulting in pneumothorax. This was the most frequent reason for hospital admission in this series. Atelectasis predisposes to pneumonitis, which was also a common recurrent finding.

Postoperatively in patients whose pleural space had been obliterated, these complications have not been noted, nor has there been a recurrence of the air spaces. Even when pulmonary function is not improved, surgery will make recurrent pneumonitis less likely, prevent pneumothorax, and curtail further enlargement of small blebs.[5]

Infection within the cyst is an infrequent finding.[7] Active tuberculosis and bronchogenic cancer have been reported as causative factors.[10,11] Of the five patients in our series who had fluid levels within the air spaces there were two proven cases of tuberculosis and one probable case.

Improvement in pulmonary ventilation and oxygen diffusion following surgery has been well documented.[2,3,9,12] If total vital capacity before surgery was depressed 25% or more and only the cysts were removed, one could expect significant increase in pulmonary function postoperatively, even though most of these patients had generalized emphysema as well. Ogilvie and Catterall[9] found postoperative improvement in patients whose air space occupied 50% or more of the hemithorax, whereas removal of small cysts did not necessarily result in better ventilation. Preoperative reduction in pulmonary function is not a contraindication for surgery when one can expect improvement with excision of the cysts.

Patients who had segmentectomy or lobectomy had a variable response to surgery, although as a group, preoperative pulmonary functions were not markedly depressed. In all instances pulmonary tissue capable of function was removed. These patients probably would have been better served had only the walls of the air spaces been removed.

Summary and Conclusion

Poor pulmonary function is not a contraindication for surgery if associated with giant bullae and/or pneumothorax.

Because giant air spaces are anatomically on the lung surface, one need not remove the lobe or lung segment.

Obliteration of the pleural space prevents pneumothorax and small bullae or blebs from expanding.

When giant bullae are found to contain fluid, one should suspect active tuberculosis.

Cerebral Vasospasm

1965*

L. M. THOMAS, M.D.**
G. P. SCRATCH, M.D.**
E. S. GURDJIAN, M.D.**
Detroit, Michigan

PRIOR TO 1950, recurring, intermittent attacks of cerebral dysfunction, frequently reversible, were thought due to focal spasm of the cerebral blood vessels. This view was succeeded by the concept of cerebrovascular insufficiency when increasing angiographic evidence of vascular occlusion and stenosis was developed. Denny-Brown, in 1951, described carotid and/or basilar insufficiency as a physiological, potential hemodynamic state, in which reversible hemodynamic crises could be elicited by any factor that impaired collateral circulation.[2]

Cerebral angiography increased its scope, demonstrating more areas of organic occlusion and stenosis. Surgical techniques were developed in order that these areas could be improved or repaired. A concept of vasospasm as a etiologic factor in the production of stroke and the treatments directed toward its alleviation disappeared almost completely; stellate ganglion block and cerebral vasodilators fell into disuse.

The concept of cerebral vasospasm was not completely lost however. Direct microscopic study of the pial vasculature by means of the Forbes window and modifications was carried out by many investigators.[5,7] There is no longer any question that the cerebral blood vessels, particularly the larger vessels about the base, respond actively to mechanical stimulation. Chemical, hormonal and metabolic stimuli are likewise effective in producing constriction and dilations.[12] The mechanism by which this vasomotor control is exerted appears similar to that responsible for vasomotor changes elsewhere in the body. Although reactive vasospasm has been the subject of many reports, the responsible mechanisms are not entirely understood.

The subject of cerebral vasospasm in relation to subarachnoid hemorrhage of ruptured aneurysm continues to attract considerable attention.[1] The mechanism of this angiospasm, sometimes local in the area of the ruptured aneurysm, sometimes general throughout the cerebral circulation, and occasionally distant from the site of rupture, has been the topic of many reports.[8] No clear mechanism has been demonstrated.

Vasoconstricting Drugs

Serotonin, angiotensin and barium chloride have been shown to produce vasoconstriction when applied to the pial vessels topically.[9] When applied in a similar manner, these same drugs will cause constriction of the major cerebral vessels about the base. The vasoconstrictor effect of these drugs has been demonstrated in the mouse, the cat and the monkey. Angiotensin has been shown to have a similar effect on the exposed pial vessels of the human.[12,13] Recent work by Ecklin, reported in New York, April, 1965, has demonstrated local vasospasm due to application of blood. Other investigators have not yet been able to reproduce this work.

Vasodilating Drugs

Inasmuch as nylidrin hydrochloride, isoxsuprine hydrochloride and papaverine are known to have vasodilating potential, these drugs were studied in topical application to the pia. All three drugs produce definite and clear vasodilation. Of the three, papaverine appears most effective. Attempts to produce vasodilation of the cerebral vessels by the intravenous administration of these compounds were somewhat more difficult. Isoxsuprine hydrochloride and nylidrin hydrochloride failed to produce demonstrable cerebral vasodilation, as determined by continuous cinemicrophotographic study, in our laboratory, even when given in doses massive enough to cause lowering of the blood pressure from generalized vasodilatation. Papaverine, on the other hand, produced vasodilatation when given intravenously. If given in large enough amounts this drug would also produce a shock state in the animal.

Attempts to block the vasoconstricting effect of barium chloride were next evaluated. Rosenbloom and Zweifach[10] were able to demonstrate reduction in the vasoconstriction caused by barium chloride if the application followed the topical use of nylidrin hydrochloride.

Method

A group comprising 25 cats and 12 monkeys were studied for the effect of topically applied vasoconstricting and vasodilating compounds. An additional five cats were utilized to study the effect of intravenous vasodilating compounds. The animals were anesthetized with phenobarbital anesthesia and the experiments were photographically recorded on 16 millimeter Kodachrome film at a four-fold magnification. Five per cent barium chloride, 0.01% serotonin and 0.05% angiotensin were used in topical application to produce vasoconstriction. These drugs were gently flowed onto the exposed pial while the vessels under study were continuously observed and recorded. Five tenths of one per cent of isoxsuprine hydrochloride and 0.5% nylidrin hydrochloride were used as topical application for vasodilation. Three per cent papaverine was used in a similar fashion.

Results

Species variation and reactivity, as reported earlier by Lende[7] and Ecklin,[3] were ap-

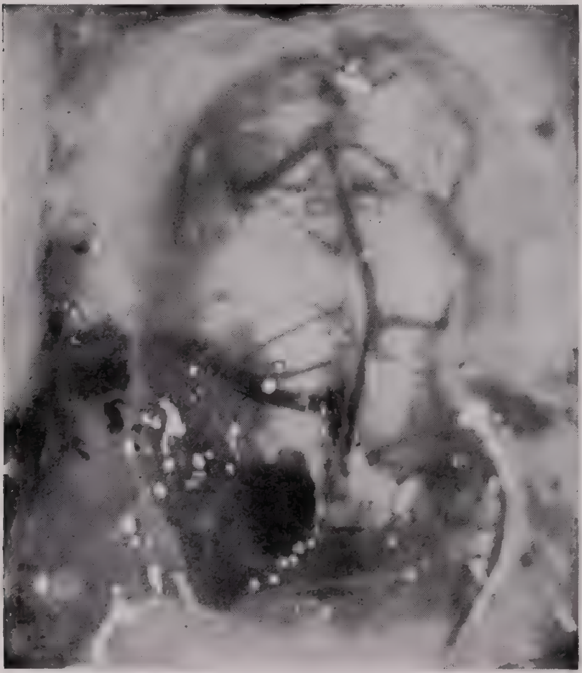

Fig. 1a — Normal basilar artery in the cat.

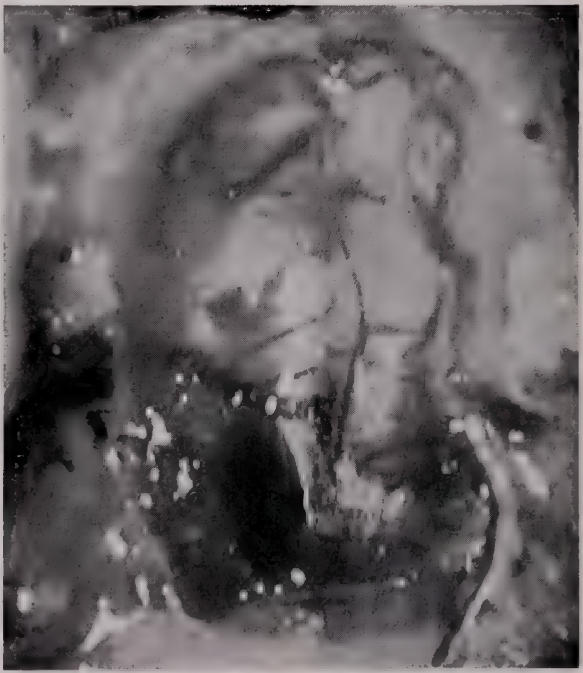

Fig. 1b — Vasoconstriction of basilar artery from 5% barium chloride.

parent. The blood vessels of the cat seemed the most reactive. Those of the monkey and human appeared to react in a similar fashion, the monkey possibly somewhat more actively. Topically applied 5% barium chloride was a potent vasoconstricting agent and resulted in marked vasoconstriction more than 80% of the time. Serotonin was nearly as effective and angiotensin appeared the least powerful. Isoxsuprine hydrochloride and nylidrin hydrochloride each produced vasodilation when applied topically. The same was true of papaverine.

When topical applications of barium chloride and isoxsuprine hydrochloride were alternated, each would counteract the other's effect and produce its own characteristic results. In the experiments related in this paper no demonstrable blocking of either substance by its opponent could be demonstrated.

Intravenous isoxsuprine hydrochloride failed to produce vasodilatation. When topical barium chloride was applied during the continuous intravenous use of isoxsuprine, vasoconstriction readily occurred.

Topically applied papaverine produced vasodilation, and this same result can be obtained with the intravenous use of papaverine. Again no blocking effect to the vasoconstricting action of topically applied drugs was noted.

Discussion

The vasomotor reaction of the cerebral blood vessels to physical, metabolic and chemical stimuli is now well documented. Reaction of the pial vessels to smooth muscle activators has been demonstrated. The pial blood vessels respond by dilation to the use of smooth muscle relaxant drugs such as isoxsuprine, nylidrin and papaverine. Although others have demonstrated a blocking effect of nylidrin hydrochloride we have, as yet, been unable to reproduce these results.

It is not clear whether the intravenous use of papaverine or similar compounds will reverse the vasospasm produced in certain cases of subarachnoid hemorrhage. It is, at this time, not possible to produce vasospasm artificially by subarachnoid hemorrhage. Recent work by Ecklin suggests that application of blood directly to the larger vessels about the base will produce definite vasospasm. Unfortunately, under the circumstances, the vasospasm does not persist for more than a

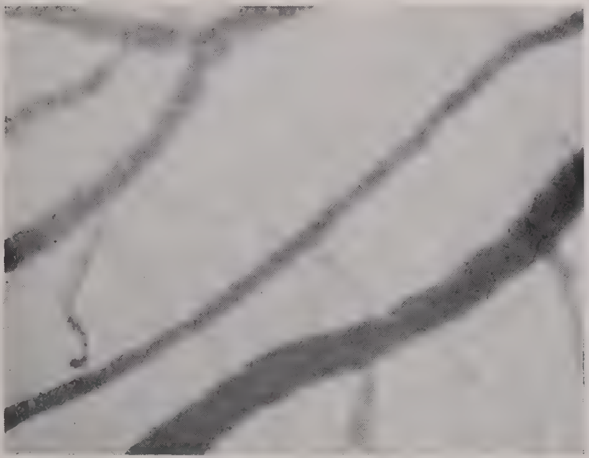

Fig. 2a — Pial vessel of 100 micra constricted by barium chloride.

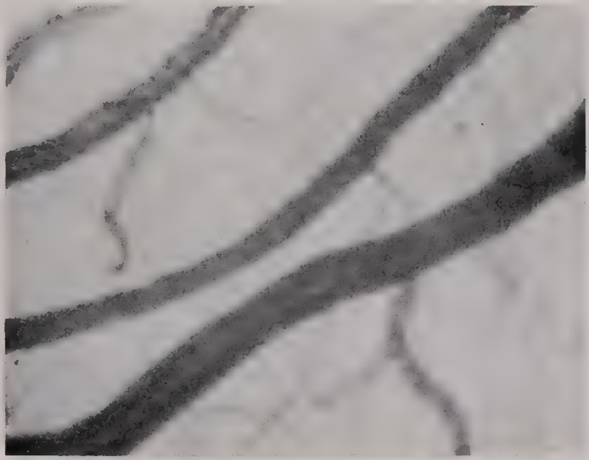

Fig. 2b — Same vessel dilated by intravenous papaverine.

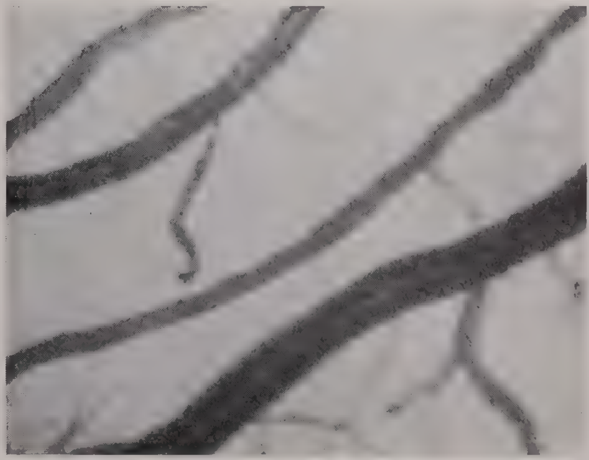

Fig. 2c — Constriction by barium chloride in spite of continous intravenous papaverine.

few minutes. Presumably such studies will require careful clinical evaluation and the use of repeated angiographic studies. It is not entirely clear whether or not the relief of the vasospasm following subarachnoid hemorrhage might result in further bleeding. Presumably this would be safe enough 12 to 24 hours after the bleed, by which time the clot should be firmly established in the rupture site.

Summary

Although cerebral vasospasm is no longer considered a cause of intermittent attacks of paralysis, weakness or dysphasia in the stroke syndrome, the effect of vasospasm in subarachnoid hemorrhage is well documented. Studies relating to cerebrovascular constricting and dilating substances have shown that barium chloride, serotonin and angiotensin produce vasoconstriction when applied topically. Nylidrin, isoxsuprine and papaverine produce vasodilation. None appears to block the effect of its opponent. Papaverine is alone in producing vasodilatation when given intravenously.

The Common People

The genius of the United States is not best illustrated in its executives or legislators, nor its ambassadors or authors or colleges or churches or parlors, or even in its newspapers or inventors — but always most in the common people. Their manners, speech, dress, friendship — the freshness and candor of their physiognomy — picturesque looseness of their carriage . . . their deathless attachment to freedom — their aversion to anything indecorous or soft or mean — the practical acknowledgment of the citizens of one state by the citizens of all other states — the fierceness of their roused resentment — their curiosity and welcome of novelty — their self esteem and wonderful sympathy — their susceptibility to a slight — the air they have of persons who never knew how it felt to stand in the presence of superiors — the fluency of their speech — the delight in music, pure symptom of manly tenderness and native elegance of soul . . . their good temper and open handedness — the terrible significance of their elections — the president's taking his hat off to them, not them to him — these are unrhymed poetry. It awaits the gigantic and generous treatment worthy of it. — Walt Whitman Leaves of Grass 1855

Iron Deficiency Anemia as Related to Zinc*

ANANDA S. PRASAD, M.D., Ph.D.**
Detroit, Michigan

IRON-DEFICIENCY anemia is a major health problem in developing countries.[1] Poor dietary intake and/or availability of iron, blood loss caused by parasites, loss of iron by excessive sweating, and geophagia† in some cases are possible reasons for iron deficiency in many countries.

Dietary Deficiency

In Iranian villages the diet consists mainly of bread made of wheat flour, with practically no intake of any animal protein, fruits or vegetables. In addition, several patients consume large quanties of clay (geophagia). It is believed that the predominantly high cereal content of the diet and geophagia, by virtue of their increased phytate and phosphate content, make the dietary iron unavailable for absorption.[2-5] Hookworm infection, which can cause excessive blood loss, is a common occurrence in the delta villages of Egypt. Loss of iron by sweating is not an important factor for persons living in temperate climates[6] but could account for at least 1 to 2 mg. of iron loss per day in normal subjects by excessive sweating in a hot climate.[7] Thus a combination of the above mentioned factors in addition to low intake of iron is responsible for high incidence of iron-deficiency anemia in developing countries.

Effect on Tissues

Tissue effects of iron deficiency in animals and human subjects have been well described.[8,9] Iron-deficient New Hampshire

†See Test Your Word Score Page 97.

chicks have white feathers instead of their normally reddish-brown plumage. The iron-deficient rat loses the deep orange pigment of its incisors; a decrease in gastric-acid secretion and an increase in the size of the caecum have been noted in rats given an iron-poor diet. The inability to absorb vitamin B_{12} by iron-deficient rats, perhaps caused by defective intrinsic factor secretion, has also been described. Rats and elephants continue to grow on iron-deficient diets and develop marked anemia during the period of rapid growth.[10]

In human subjects, iron deficiency causes changes in the mucosa of the alimentary tract.[8,11] The oral mucosal epithelium is abnormally thin in some patients. Mitoses in the prickle-cell layer are more frequent in iron-deficient than in normal subjects. Melanin deposition is less, and subepithelial inflammation is increased.

Clinical Manifestations

Changes in the esophagus of iron-deficient patients give rise to "sideropenic dysphagia."* Constrictions or webs of the hypopharynx or esophagus result in inability to swallow solid food.[12] Histopathologic findings have included keratinization of the lingual epithelium and leucocytic infiltration of the submucosa. Atrophy, hyperkeratinization and changes resembling leukoplakia have been described in the esophageal mucosa. The esophageal lesions of iron deficiency have been regarded as precancerous.

Gastric atrophy and achlorhydria are commonly associated with this disorder.[13] Changes vary from superficial to atrophic gastritis. It is unclear whether these are the results of iron deficiency or whether they are of etiologic significance in development of hyposideraemia.

In blood, unrelated to decreased hemoglobin synthesis, one may find leukopenia, thrombocytopenia and a poorly defined bleeding tendency.[14]

Koilonychia* has been observed in iron deficiency. It has been suggested that a dietary cystine deficiency may be important in the development of this abnormality.[8]

A large number of individuals in Egypt have low serum iron, high unsaturated iron-binding capacity and low normal hemoglobin level. Similarly, patients with iron-deficiency anemia would recover promptly within three to four weeks of iron therapy so far as the hemoglobin and hematocrit were concerned, but their serum iron would remain essentially unchanged for several weeks in spite of therapy.[3] This emphasizes that in a population where the nutrition with respect to iron is basically inadequate, a near normal hemoglobin level does not indicate normal tissue iron saturation as judged by serum iron and unsaturated iron-binding capacity determinations. These subjects, however, develop marked anemia due to added blood loss when they get infected with hookworm.

Zinc-Deficiency Syndrome

Zinc is an essential nutrient factor for both plants and animals. Its essentiality for growth in plants was established in 1926; in 1934 it was first demonstrated that zinc was essential for growth in the rat. The clinical features of zinc deficiency in rats were first described in 1941, in pigs in 1955 and in poultry in 1958.[15]

Clinical Manifestations

During our studies in Shiraz, Iran, we encountered a group of adult males who presented the following clinical picture: severe iron-deficiency anemia, hepatosplenomegaly, hypogonadism, dwarfism and geophagia. Their diet consisted mainly of bread made of wheat flour with practically no intake of animal protein. These patients showed no blood loss and no evidence of malabsorption.[2]

Since iron deficiency alone does not produce retarded growth and sexual hypofunction, it appeared likely that other associated deficiencies may have been operating. The content of iron and zinc in most foodstuffs parallel each other; both metals are complexed with phosphates and phytates, thus making them unavailable for absorption. Both are present in high concentration in red cells. Therefore in chronic blood loss one may expect both deficiencies. Sweat excretion in tropical climate may account for 1-2 mg. of zinc loss per day, similar to that of iron loss.[7] Furthermore, the growth failure and testicular changes observed in these dwarfs appeared very similar to those encountered in zinc-deficient animals.

---

*See Test Your Word Score Page 97.

Subsequently our studies in Egypt indicated that similar subjects with identical clinical features were zinc-deficient.[3,4] Seventeen such patients who came from the delta villages near Cairo, Egypt, were studied in detail. Clinically they showed the same features as previously described for Iranian patients; their growth was retarded, and all had hypogonadism, hepatosplenomegaly and iron-deficiency anemia. Their diet consisted mainly of bread and beans (vicia fava), with negligible intake of animal protein. They differed from the Iranian group in that they all had schistosomiasis and hookworm infections; but geophagia was not observed.

Nutritional zinc deficiency in human subjects had not been recognized prior to our observations. In patients with liver cirrhosis, hyperzincuria is present, resulting in decreased levels of zinc in the plasma and the tissues.[15] Our subjects in Iran and Egypt had no evidence of cirrhosis of the liver.[18] The Egyptian subjects had granulomas in the liver due to schistosomiasis but did not have portal cirrhosis. Their liver-function tests were unremarkable except for the changes in the serum alkaline phosphatase, to be discussed later and their excretion of zinc in the urine was less than in normals. Thus we concluded that in our cases liver disease was not a factor in the production of zinc deficiency.

Metabolic Studies

Zinc metabolism studies in these subjects indicated that zinc content of plasma, red blood cells and hairs were reduced as compared to the normals (Table 1). Zinc-65 studies revealed a decreased plasma disappearance rate in the initial phases, a rapid

4. Excretion of Zn^{65} in urine in 13 days in % of dose administered.	2.80 ± 0.56	1.60 ± 0.68	$P < .01$

turnover rate, and a decreased 24-hour exchangeable zinc pool in the dwarfs as compared to the normals (Table 2). The excretion of Zinc-65 in urine and stool was less in the dwarfs. All these data were considered as evidences of zinc deficiency in this group of subjects.

Treatment

In every case, following adequate treatment, the serum alkaline phosphatase increased markedly. Similar phenomena in zinc-deficient animals after treatment have been reported.[19] Alkaline phosphatase is a zinc-containing enzyme. The increased activity of this enzyme following treatment may possibly be the result of increased availability of zinc for its synthesis. Alkaline phosphatase increases with increased growth hormone levels. Thus the increasing level of this enzyme may be indicative of increased production of growth hormone following treatment.

Diet and Iron

The Iranian patients were treated with oral ferrous sulfate and good hospital diet. Their hemoglobin became normal within six to eight weeks. The size of the liver and spleen decreased, and pubic hair appeared with an increase in growth. Three of the patients who were followed after a year had developed a normal growth pattern and had normal sexual development. However, since commercial iron preparations contain appreciable amounts of zinc, one could not be certain if these manifestations were being reversed because of the iron or the zinc administration.

Experimental Treatment

To establish a relationship further, the Egyptian patients were kept on wards of U. S. Naval Medical Research Unit No. 3 in Cairo for prolonged periods of observation under treatment with reagent grade pure iron or zinc. Careful measurements of their height along with their clinical, hematological and biochemical status were determined at suitable intervals.

Adequate Protein and Calories

Two subjects were kept on good diet (adequate in animal protein and calories) for 12 weeks but received no supplemental iron or zinc. Both gained one inch in height during this period, and their plasma zinc increased significantly.

Adequate Diet and Iron

At the end of this period, one of them was started on iron and the other received zinc. The patient on iron grew one inch in 14 weeks, whereas the one on zinc grew one inch in 10 weeks. Another patient received iron for 16 weeks without any change in height, and the third patient on iron gained 1¼ inches in 24 weeks. The size of the genitalia remained unchanged, and no growth in pubic hair occurred in patients receiving iron treatment; but their anemia was fully corrected.

Adequate Diet and Zinc

On the other hand two other patients on zinc gained 1 and 1.6 inches in height during seven weeks, whereas a third gained 2 inches in 10 weeks of zinc therapy. All four subjects on zinc showed a remarkable increase in size of their external genitalia and grew dark pubic hairs during the period of observation; but they remained anemic. The majority of the patients had roughened hyperpigmented skin mainly in exposed areas, which promptly cleared following treatment with zinc supplement and good diet. The excretion of follicular stimulating hormone in urine increased remarkably following zinc treatment. In addition serum alkaline phosphatase increased, and hepatosplenomegaly became less prominent in patients receiving zinc as compared to those on iron. Thus, under the conditions of our experiments, the rate of growth was greater, the genitalia size increased, and pubic hairs appeared in patients who were treated with zinc as compared to those who received iron treatment.

Vitamins and Other Trace Elements

Serum levels of Vitamin B_{12}, C and A were normal. No evidence of folic acid or B_6 deficiency was obtained as determined by the formiminoglutamic-acid and xanthurenic-acid excretion tests.[3] Copper level in serum was slightly increased, and serum magnesium was normal.

Zinc Deficiency

Thus our detailed investigations revealed that two factors were complicating the clinical features in these subjects: the first, iron-deficiency anemia, and the second, zinc deficiency. The possibility that severe anemia alone could account for the retardation of growth and hypogonadism was considered. However, our studies in Kharge oasis indicated that a group of patients with this syndrome were only mildly anemic because they had no blood loss due to parasitic infestation, but their serum zinc levels were decreased, thus indicating that anemia alone was not a factor in affecting the growth and gonadal development.[5] Growth retardation and sexual hypofunction do not occur in experimental iron-deficient animals. On the other hand these features are constantly observed in animals made zinc-deficient.

Hypogonadism

I appears therefore that zinc deficiency in these human subjects was probably responsible for growth retardation and hypogonadism.

Hormone Deficit

In all our patients in Egypt the urinary 17 hydroxycorticoids were low normal, but 17 ketosteroids excretions were decreased. Follicular stimulating hormone excretion in urine was low in all cases. In some patients the endogenous production of adrenocorticotropic hormone was decreased.[20] Thus pituitary hypofunction was evident with respect to growth hormone, gonadotropic and adrenocorticotropic hormone activities. Serum protein-bound iodine was normal, indicating normal thyrotropic activity.

Comments

Since the investigations on the patients with hypogonadism and dwarfism suggest that zinc plays a highly significant role in human nutrition, and since zinc deficiency in plants and animals has been well documented, it appears reasonable to predict that certain poorly understood clinical disorders in man, not yet recognized as being related to abnormalities of zinc metabolism, may actually be so related.

For example, koilonychia, considered to be a cardinal sign of chronic iron deficiency, has been noted in experimental zinc deficiency in animals. Likewise esophageal changes occur in these animals. It is possible therefore, that the esophageal "web" of the Plummer-Vinson syndrome* may actually be a manifestation of associated zinc deficiency.

Thus it is timely to re-evaluate some of the manifestations of chronic iron deficiency as being possibly related to associated zinc deficiency. When we consider the close similarity between iron and zinc in relation to such features as body content, serum and red-cell concentration, and possible absorption mechanisms, this relationship becomes a significant possibility. However, this must be considered speculative until further research provides answers.

It is evident, then, that in patients with nutritional iron-deficiency anemia, one must also look for associated zinc deficiency. A recognition of this association will stimulate further research in this area, which will ultimately clarify specific tissue effects of iron and zinc deficiencies. Even in animal experiments, critical studies to differentiate tissue effects of iron deficiency are lacking, and one must therefore evaluate results accordingly.

Our patients in the Middle East consumed a high cereal diet. According to our analysis a sample of Iranian wheat contained 0.66% of phytate; seventy-one per cent of the total phosphorus in this wheat was phytate phosphorus. Presence of phytate makes zinc less available for absorption;[21,22] therefore we believe that high phytate content in the diet must be a major factor in production of this deficiency.

We obtained no evidence for copper deficiency in our patients. This would indicate that copper was adequate and available in their diet. Copper and manganese are present in large quantities in cereals, and the effects of phytate on these trace metals are not nearly as pronounced as in the case of zinc.[23] Furthermore, our patients did not present any clinical similarities to those in animals suffering from these deficiencies.

---

*See Plummer-Vinson Syndrome Page 64.

We did not measure serum cobalt in our patients. However, the anemia in all patients responded to iron administration only. Furthermore, the severe emaciation evident in cobalt-deficient animals was not noticed in our subjects.

It is clear that more work needs to be done in order to define availability of these trace metals in diets normally consumed. Some studies concerning this problem are presently in progress in Egypt.

Summary

A group of patients from the Middle East, exhibiting iron-deficiency anemia, hepatosplenomegaly, dwarfism and hypogonadism, were studied extensively and found to have zinc deficiency as well as iron deficiency. This is the first description of nutritional zinc deficiency in human subjects. Our studies strongly suggest that dietary zinc deficiency in man can cause extreme retardation of growth and of gonadal development.

In Shiraz, Iran, severe iron-deficiency anemia was encountered in adults in the absence of any blood loss and/or malabsorption syndrome, thus indicating that their cereal diet and geophagia most likely made the iron unavailable for absorption.

PLUMMER-VINSON SYNDROME

Dysphagia, atrophic changes in the buccal, glossopharyngeal, and esophageal mucous membranes, spoon-shaped nails, and a microcytic, hypochromic anemia are the characteristic features of this syndrome, first described by Plummer in 1914. It occurs predominantly in middle-aged women.

Anemia is usually present and sideropenia is normally found. There may be a dry mouth and pharynx and a sensation of nasal obstruction, evident for a number of years before the onset of the anemia.

Dysphagia is a conspicuous symptom. There may be associated stomatitis, glossitis, cheilitis, hypochlorhydria or achlorhydria, splenomegaly, and spoon-shaped brittle nails. A weblike filling defect at the upper end of the esophagus has been observed, which disappears after therapy.

There is a tendency for these patients to develop oral pharyngeal cancer.

Neonatal Gastric Rupture

ALLEN SILBERGLEIT, M.D.*
ERNEST M. BERKAS, M.D.*
Dearborn, Michigan

SPONTANEOUS GASTRIC rupture in the newborn has until recently been considered a rare condition. However, it is the most common of visceral perforations in infants, and a total of 168 cases with 43 survivals have now been reported. The purpose of this report is to document a recent case, point out the diagnostic features and describe the pathology. In addition, a mechanism responsible for this phenomenon based on experimental work in dogs is proposed.

Case Report

This 5-pound white female infant was born November 30, 1961, following a 38-week gestation. Delivery was somewhat difficult as a result of a compound presentation. However, there was no evidence of fetal hypoxia. The baby did well for three days and passed meconium stool. However, on December 3, 1961 (approximately 68 hours after birth), she developed abdominal distention, failed to take food, vomited and became lethargic.

Physical Findings

Examination of the heart and lungs was noncontributory, but there was moderate respiratory distress which appeared to be secondary to the abdominal distention. The abdomen was resonant to percussion; there were no bowel sounds. There was edema of the parietes. Rectal examination was normal. Hemoglobin was 17.5 grams per cent and white blood count 2,150 per cubic mm. Roentgenograms of the abdomen showed pneumoperitoneum (Figure 1). The diagnosis of a ruptured hollow viscus was made and the infant taken to the operating room.

Operative Findings

A catheter was placed in the saphenous vein at the ankle and exploratory laparotomy carried out under general anesthesia. A longitudinal tear of the anterior wall of the stomach was seen. It measured 7 cm. in length, involved the fundus and body and extended to the antrum. A narrow margin about the gastric defect was necrotic. A whitish and somewhat adherent material which appeared to be infant for-

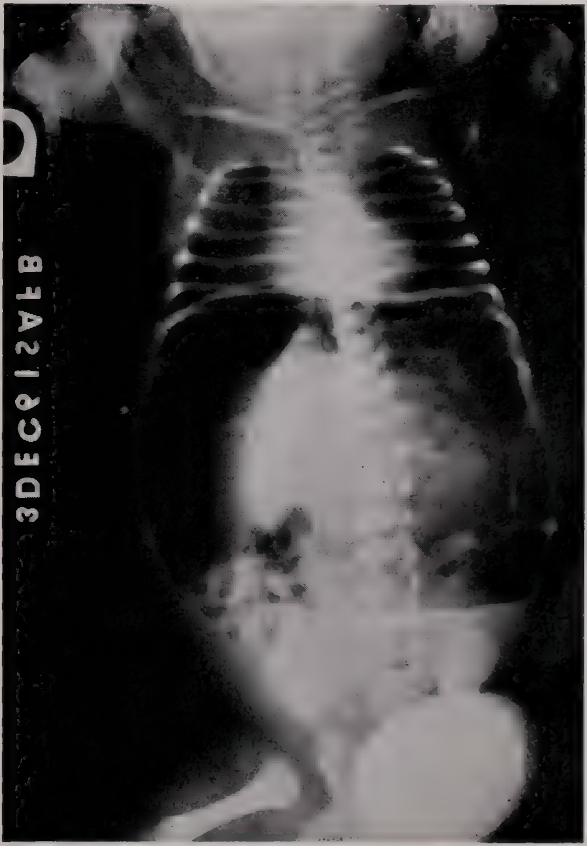

Fig. 1 — Upright roentgenogram. Note the "saddle bag" configuration of the air density.

---

*Departments of Surgery, Veterans Administration Hospital, Dearborn, Michigan, and Wayne State University School of Medicine, Detroit.

mula coated both the visceral and parietal peritoneums. This material was picked off. There appeared to be an early generalized peritonitis. Debridement of the lacerated margin was then carried out and the gastric defect repaired with a 2-layer closure. (Microscopic section of material excised from the margin showed acute inflammation and amorphous debris.) Following closure, the stomach was reduced in size and had a tubular appearance. The peritoneal cavity was thoroughly irrigated with saline and the abdominal wall closed. No drains were placed. The patient's postoperative course was uneventful. When seen three years later, she was a bright little girl with normal growth and development.

Comments

A ruptured hollow viscus should be suspected in the newborn with the clinical picture described.

Pneumoperitoneum

Gastrointestinal dilatation also causes abdominal distention, but pneumoperitoneum seen on upright abdominal roentgenogram confirms the diagnosis of visceral disruption. It is not possible to localize the ruptured viscus with absolute certainty in any particular case. However, an impressively constant picture is seen when gastric disruption occurs in neonatal life. This patient conforms to the pattern generally described for this entity, except for the sex incidence in which males predominate with a ratio of 1.5 to 1.0.

Prematurity

Characteristically, these infants who may be premature do well for two to four days following birth. They take feedings and pass normal stool.

Sudden Onset

Then there is a sudden onset of lassitude, abdominal distention, and dyspnea, followed by paralytic ileus, dehydration and shock. Massive pneumoperitoneum is seen by x-ray. In the upright film, the striking appearance of the air outline has been called the *saddlebag* configuration.[1] Studies with barium or other radiopaque media should not be done. Since they are not necessary for diagnosis, they delay treatment and add more foreign material to the peritoneal cavity. The evidence of a visceral perforation within the first four days of life in a newborn who had been doing well should lead to a presumptive diagnosis of gastric rupture. More distal visceral perforations *usually* occur in older infants. Also, gastric rupture is more likely to occur on a statistical basis, since all reported disruptions of the duodenum, remaining small bowel, and colon in the newborn total less than the number of gastric disruptions.[2]

Treatment

Treatment for rupture of any hollow viscus in the newborn is the same, and except for placement of the incision, preoperative localization of the perforation site is not essential. Intravenous fluids, gastric suction, and antibiotics should be started at once and laparotomy performed. Surgical closure of the perforation is then carried out, since the omentum in the newborn is small and thin and unlikely to seal any perforation. A careful inspection of the viscera should be made, because multiple perforations have been described. It is not necessary to drain the peritoneal cavity.

Several cases of pneumoperitoneum have been described where the source of free air could not be identified.[3] The term "spontaneous pneumoperitoneum of the newborn" has been suggested for this entity. The few infants who have survived pneumoperitoneum without operation probably belonged in this category.

Only 10 cases of gastric disruption were reported in the century following the first description of the entity in 1825.[4] However, within the past 15 years a considerable number have appeared in the world literature. An attempt at closure of a perforated stomach in infancy was made by Stern[5] in 1929. Leger,[6] who operated and reported on his case in 1950, is credited with the first successful repair. Ross[7] and Kellogg,[8] at about the same time, described operative treatment with survival.

Etiology

The etiology of spontaneous gastric rupture in the newborn is not known, although a number of causes have been proposed.

Peptic Ulcer

Until several years ago, most gastric disruptions were assumed to be due to peptic ulcer, although Herbut[9] in 1943 had already described a congenital defect in the muscle of the stomach wall in some of these cases.

Most gastric disruptions in the newborn have the appearance of a long linear and ragged rupture or laceration rather than a perforation, and most occur on the fundus or greater curvature. A "punched out" type of lesion is less frequently seen, and even these do not show the intensely acute and chronic inflammation characteristic of peptic-ulcer perforations.

Distal Obstruction

Distal obstruction has been present in several cases and various congenital anomalies have been described, but there is no predominant associated defect. Gastric disruption may occur with duodenal atresia, although this is uncommon. It has not been reported with hypertrophic pyloric stenosis. Ruptured gastric diverticula have been described in a few cases.

Trauma

A number of cases of gastric trauma and perforation have been described. Most of these were the result of intubation with a staff catheter, or air-oxygen administered under pressure by means of a face mask. This group of perforations should not be called "spontaneous." Lloyd[2] has recently implicated fetal anoxia as an etiologic factor.

These studies were stimulated because the gastric disruption in this case and in most of the other cases reported[1] appears comparable morphologically to a distention-bursting type tear. Most of these disruptions occur in the fundus or on the greater curvature which has lower local bursting strength than the lesser curvature or antrum-pyloric area during the first decade of life.[10]

Experimental Studies

In 10 dogs the esophagus and stomach were removed and a tube inserted into the stomach via the esophagus. The pylorus and distal esophagus were ligated. Pressure within the stomach was monitored as the stomach was distended with air or water. In the remaining dogs, esophagus and stomach were left in situ, and celiotomy was done to ligate the pylorus and distal esophagus. The abdominal wall was left open in 21 dogs and closed in 72. A mean intraluminal pressure of 142 mm. Hg. caused rupture of the stomach when isolated, or when the abdominal wall incision remained open and there was no impeding of the huge dilation. With the stomach expansion limited by closure of the abdominal incision, a mean 196-mm. Hg. caused rupture.

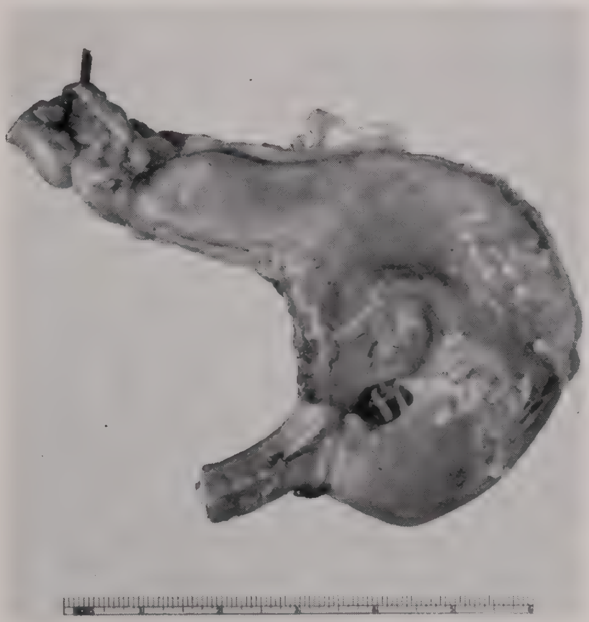

Fig. 2 — Dog study. This gastric rupture is located on the posterior wall near the esophagogastric junction.

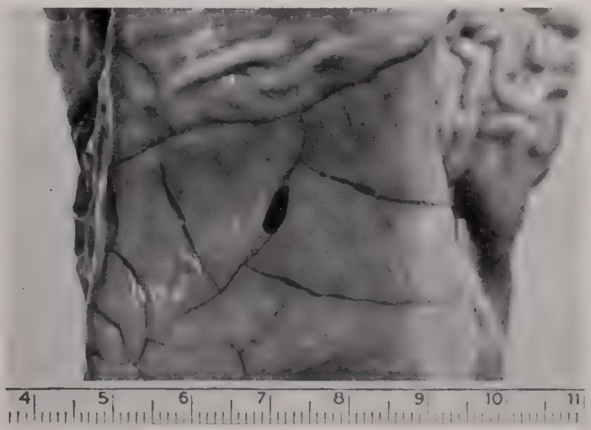

Fig. 3 — Dog study. Disruption is viewed from within the opened stomach. Note "cracks" in the mucosa. The submucosa split along one of the mucosal lines of injury.

External pressure applied to the abdomen caused rupture of partially inflated stomachs. No differences in bursting pressures or other rupture characteristics could be determined for normal anesthetized, anoxic, or recently sacrificed animals. Also, ruptures were similar in the air and the water-distended stomachs. The anterior wall was ruptured in a slightly larger number of cases than the posterior wall. Only 22 disruptions occurred at or near the lesser curvature, while most were found at or near the greater curvature. Some occurred near the esophagogastric junction (Figure 2), but the antrum never ruptured. Disruptions in all groups were similar in appearance. Only four dogs had small (1-2 mm.) perforations, while the remainder had large rents up to 6 cm. in length. The seromuscular coat splits first, followed by tears in the mucosa and finally in the submucosa (Figure 3). The submucosa is the strongest stratum of the stomach wall and the last to tear.

Perforation characteristics following air or water distention strongly resemble the "spontaneous" gastric rupture of the human newborn. The tears in the dog-stomach were similar in appearance to those seen in the infant and were located in the body of the stomach where the diameter is greatest. This is consistent with known stress variability in cylindrical objects. The greatest stress is present in that position of a tubular structure which has the greatest diameter. This may be expressed as:

$T = piDP$ T is the tension, while D is the diameter in centimeters and P is the intraluminal pressure in centimeters of water.

This is the same relationship pointed out by Wangensteen[11] in his study of perforation of the cecum in adults.

Conclusions

Diagnosis of a perforated viscus in the newborn should be suspected clinically and confirmed by x-ray film of the abdomen. Most visceral disruptions during this period occur in the stomach, and preoperative localization of the defect can be made with a fair degree of assurance. Our case demonstrates that even the huge ruptures can be adequately treated and the three-year follow-up shows no untoward growth and development.

Our experimental studies suggest that a fetal stomach, partly filled with fluid (swallowed aminotic fluid) and subjected to the rigors of the birth canal during a difficult delivery, may develop an intraluminal pressure sufficiently great to cause a gastric-wall defect. This defect could lead to complete disruption within a few days as the infant swallows liquid and air to further distend the stomach. The infant's air-swallowing characteristics and the need to eructate are well known.

Erosion of the Splenic Artery from Gastric Ulceration

WALTER R. BREWER, M.D.*
RAYMOND C. READ, M.D., F.A.C.S.**
Detroit, Michigan

GASTRIC ULCERS occur less frequently than their duodenal counterpart, but their tendency to give rise to massive hemorrhage is greater.[10] The site of bleeding is generally granulation tissue or erosion of intramural vessels, although involvement of major vessels, particularly one of the gastric arteries, is well known.[1,3,4,9]

We have recently observed three cases of catastrophic upper gastrointestinal bleeding resulting from ulceration of the splenic artery. In one the ulcer was benign, in the other two, malignant. All lesions were unusually large, located high on the posterior wall, and extending deeply into the pancreas. Review of the recent literature provided seventeen instances of hemorrhage from rupture of a splenic aneurysm into the stomach.[5,8,12] Involvement of a nonaneurysmal splenic artery by gastric ulcer erosion is mentioned only once.[6] The purpose of this report is to point out that large, chronic gastric ulcers may give rise to exsanguinating arterial hemorrhage, which must be treated by immediate surgery if the patient is to survive.

Case Reports

Case 1.

This 43-year-old white woman entered the hospital complaining of intermittent hematemesis for the two days preceding admission. There was a past history of bleeding after alcoholic excess. The hemoglobin concentration was 8.8 grams%, and the blood pressure, 80/50 mmHg. She was pallid and sweating. One thousand ml. of whole blood was given and

**Associate Professor in Surgery, Wayne State University School of Medicine.

nasogastric lavage performed until return was clear. She was then begun on a milk-drip regimen and carefully watched for evidence of renewed bleeding. Her condition remained stable for 48 hours, at which time she began to bleed massively, went into profound shock, and appeared moribund.

Immediate laparotomy was performed. The stomach was emptied of clots by gastrotomy, and the bleeding site was identified in a huge gastric ulcer high on the posterior wall of the stomach. The bleeding was controlled by digital pressure while her blood volume was replaced and anesthesia induced. The bleeding vessel was initially thought to be the left gastric artery, and while an assistant controlled the bleeding point, the celiac axis was rapidly dissected out and the left gastric artery ligated at its origin. This failed to control the bleeding and further dissection showed the vessel involved to be the splenic artery, which was then ligatured proximally and distally with cessation of bleeding. Biopsies of the crater showed a benign ulcer. A 75% gastrectomy was performed with a Billroth 1 anastomosis, the patient receiving a total of 16 units of blood on the day of operation. Her convalescence was complicated by the development of both gastric and jejunal fistulae. After prolonged hospitalization, she was discharged and, at the time of this reporting nine months postoperatively, she has regained her weight and pursues full activity.

Case 2.

This 50-year-old white male entered the hospital because of weakness, melena, and burning epigastric pain of two to three months' duration, his symptoms having become worse on the two days preceding admission. When initially evaluated in the Emergency Room, his blood pressure was 80/60 mmHg., pulse rate 112 per minute, and his hemoglobin concentration 8.3 grams%. He was given three units of blood and his stomach showed a clear return after lavage with saline. He was then begun on a continuous milk drip and observed for signs of further bleeding by nasogastric lavage, monitoring of vital signs, character of the stool, and hematocrit. Over the course of the next nine days no further bleeding ensued, and two upper gastrointestinal tract barium studies were carried out and reported as normal. Two days after the second set of x-rays, the patient began to bleed actively and required emergency laparotomy. At surgery, a giant ulcer measuring 8 x 10 cm. was found high on the posterior wall of the stomach with an arterial bleeder at its base. Dissection in the area showed that the splenic artery was the source of bleeding. This vessel was ligated; biopsies of the ulcer were taken; the ulcer was oversewn, and a vagotomy and pyloroplasty were performed. Frozen section diagnosis of the biopsies was benign, but permanent sections showed malignant foci. This patient also received 16 units of blood on the day of surgery. He has since been readmitted and re-explored. Widespread metastases at the time of the second operation precluded further resection.

Case 3.

This 60-year-old white male was admitted to Sinai Hospital, Detroit, in February 1965 because of epigastric pain, weight loss, intermittent nausea, and vomiting. During his evaluation, a large gastric ulcer was found on upper gastrointestinal series, and the patient underwent laparotomy. A malignant ulcer high on the lesser curvature was found, with metastases in the retroperitoneal space. Due to the extent of the lesion, it was not resected. He was well until March 1965, when he was admitted because of hematuria, and subsequently developed epigastric symptoms. Hematemesis first occurred four days prior to his demise and was mild in degree. His terminal event was a sudden, massive hematemesis.

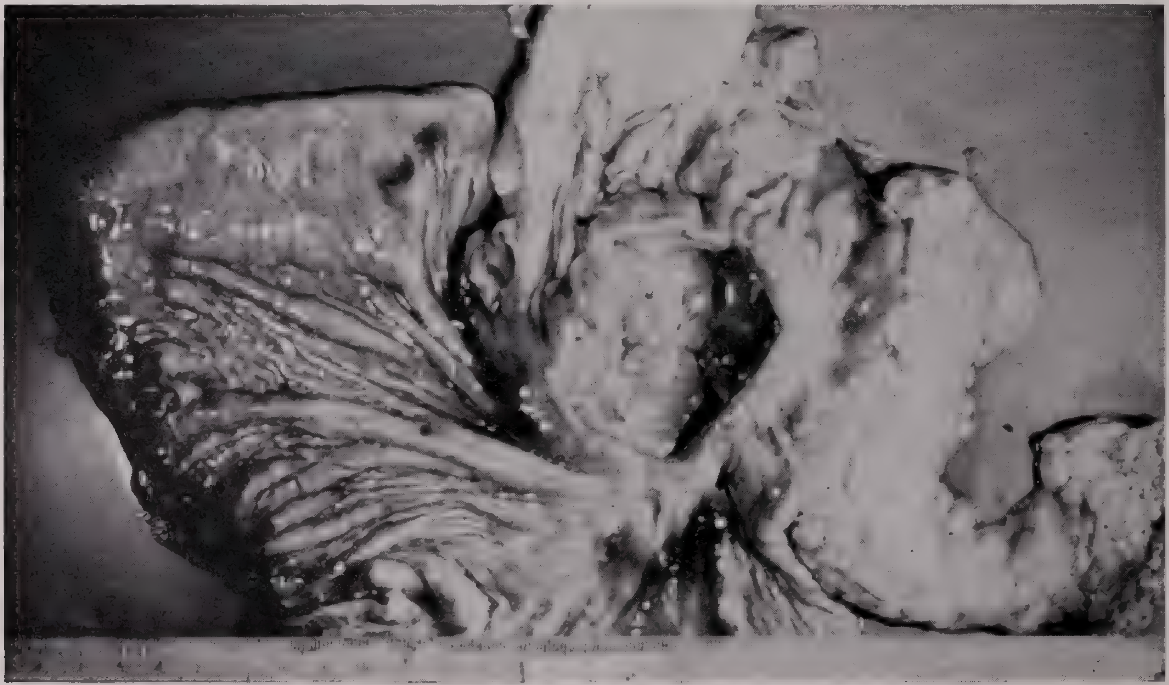

Fig. 1 — Stomach, Case 3. Large ulcer crater near esophageal junction. Pancreas is seen at right.

At autopsy, a large malignant ulcer high on the lesser curvature was found, with penetration into the pancreas and erosion of the splenic artery. Hematuria was due to a clear cell carcinoma of the left kidney.

Discussion

In most instances, gastrointestinal bleeding from peptic ulceration can be managed without immediate surgery.[1,7,10,11] In a few cases, due to the hazard of exsanguination, emergency operation is mandatory. When bleeding of such magnitude occurs. large vessels are likely to be involved. The arteries most often eroded are the gastroduodenal and left gastric.[10]

The rarity of reports of splenic artery erosion by either benign gastric ulcers or gastric carcinomas may be related to several factors. In surgery of massive upper gastrointestinal hemorrhage, the bleeding must be rapidly controlled if the patient is to survive. In Cases 1 and 2, each patient received 16 units of blood at surgery. Thus the urgency of hemostasis may outweigh the desire for delineation of the source of bleeding. Some cases of fatal hemorrhage from splenic artery erosion are not documented, because immediate surgery was not undertaken and postmortem autolysis obscured the bleeding point at autopsy. Since these same factors apply also to other name vessels which have been reported as the site of hemorrhage, other features unique to the splenic artery must be operative. The majority of gastric lesions, both benign and malignant, occur in the distal half of the stomach and thus are separated by some distance from the splenic artery. The course of this vessel, being superoposterior as well as lateral, further enlarges the distance between it and the posterior stomach wall. Thus, if an ulcer is to involve this artery, it must penetrate deeply into the pancreas.

Hemostasis may often be very difficult in these cases. Obviously, massive volume replacement is required and immediate operation necessary. The responsible vessel may not always be apparent and the best management of the problem not obvious. We have used both ligature of the vessel proximal and distal to the ulcer, and oversewing the vessel in the ulcer crater; we have found the former method preferable. While an assistant achieves control by digital pressure in the crater, dissection of the celiac axis and ligature of the splenic artery is carried out. The bleeding controlled, volume replacement and further operative procedures may then be

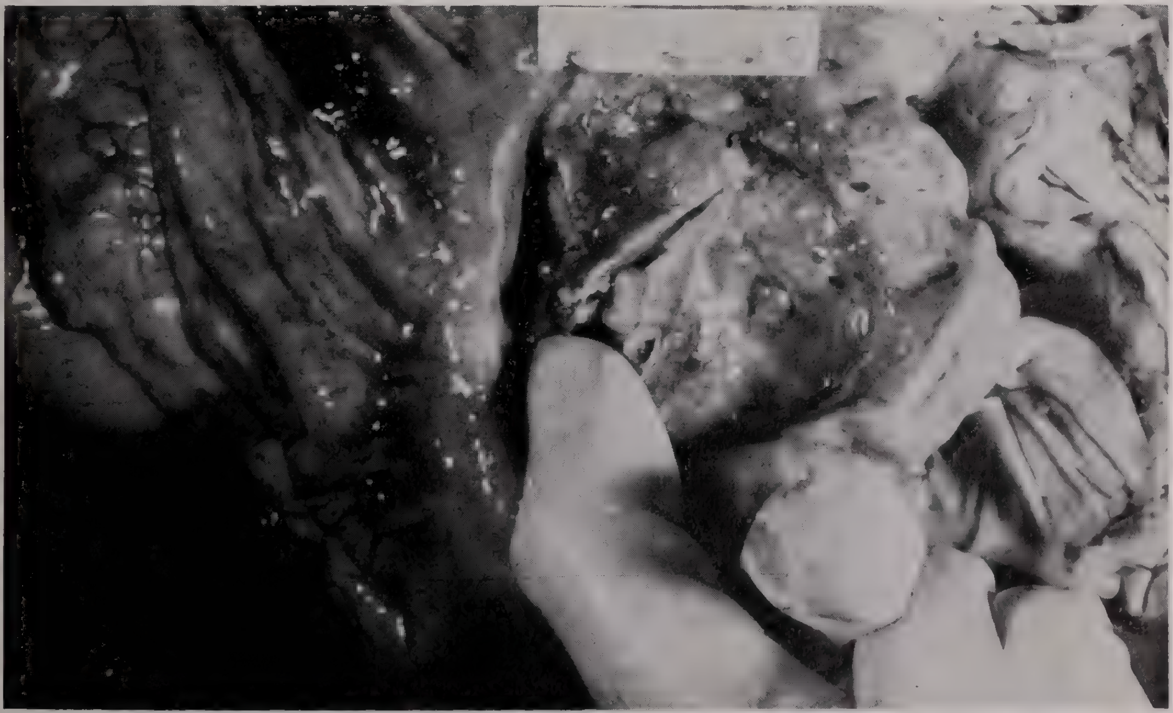

Fig. 2 — Stomach, Case 3. Splenic artery demonstrated in base of ulcer.

undertaken. With either method, development of pancreatic fistula is a possibility in the postoperative period. We have been impressed with the extraordinary size of these ulcers; all three measured 8 cm. in diameter. This, together with involvement of large portions of pancreas, suggests chronicity, although the history in all cases was brief. It has been said that lesions in the upper stomach give rise to fewer and less severe symptoms than those nearer the pylorus;[9] certainly the capacious fundus could hardly be the source of obstructive symptoms. These factors may explain the huge size of the ulcer and apparent procrastination of the patient in seeking treatment. In each of these cases a preliminary, less severe bleeding episode preceded the massive one. Such "sentinel bleeds" have been described when large vessels are the site of hemorrhage.[2]

Radiologic examination is rarely helpful in these individuals; the diagnosis is made at laparotomy. In Case 2, upper gastrointestinal series on two separate occasions were read both initially and retrospectively as normal, despite the presence of a huge ulcer. Perhaps the size of the ulcer or presence of clot within its crater precludes recognition. The poor condition of the patient with truly massive bleeding certainly prohibits detailed preoperative evaluation.

The differentiation of malignant from benign lesions under circumstances imposed by emergency surgery is difficult. Frequently, frozen sections are not available during the night and final diagnosis of stomach tissue may require permanent sections. Most large, deeply penetrating ulcers grossly appear malignant, regardless of their true nature. In the absence of metastases, some ulcers must be treated as benign, the immediate bleeding situation remedied and definitive surgery deferred until a final diagnosis is made. This is particularly true when the patient is moribund, when massive transfusions have been given, and when limitation of further anesthesia is desirable.

Summary

Of the three cases of massive upper gastrointestinal hemorrhage from ulceration of the splenic artery malignancy accounted for two. The features which suggest splenic artery involvement are a huge ulcer, high on the posterior stomach wall, with deep penetration into the pancreas. Chronicity is certainly suggested by these factors, although the history was brief in all three cases. Premonitory "sentinel bleeding" before the massive, frequently fatal, hemorrhage is common, and an aggressive surgical approach is required.

We wish to thank Drs. Eugene Copuzzi and Molly Lo of Sinai Hospital, Detroit, for permission to use Case 3 and for providing material helpful in this presentation.

Alarming

America is not immortal and there are today signs in American life of an alarming deterioration in the things of the spirit. — Francis Cardinal Spellman

The Doctor and Literature

Literature is thought in words committed to permanent form by writing. Unlike other art forms like painting or acting, it never decays and never deteriorates.

The lot of the creative writer, like Gilbert's policeman in the *The Pirates of Penzance*, is not a happy one. The author is bedevilled by his God-given talent which never allows him to be at peace with himself. His mind seethes with ideas clamoring to be set down in writing.

> "The poet's eye in fine frenzy rolling
> Doth glance from heaven to earth, from
> earth to heaven
> And as imagination bodies forth
> The form of things unknown
> The poet's pen turns them to shapes
> And gives to airy nothing a local
> habitation and a name."

Because he lives in the world of his own imagination the writer is usually at odds with the age in which he was born into a world he never made. Many authors like St. Paul are born out of due time.

Creative geniuses are frequently feared and hated by their contemporaries, who persecute them during their lifetime and praise them extravagantly after death. The creative writer has a vast and warranted egotism which often makes him rude and inconsiderate of the feelings of others. He is usually impossible to live with. Shakespeare and Dickens both deserted their wives for younger women. Milton called his wife a "mute and spiritless mate, a bit of earth and phlegm.' And the long suffering Mrs. Carlyle, after a lifetime with Thomas, said that a genius was "gang ill to live with."

A writer like Sinclair Lewis may enjoy sudden prosperity and success early in his career and never be able to duplicate his triumph. Too often sudden fame and fortune are followed by a dismal anticlimax of years of neglect and oblivion. The author often dies unwept, unhonored and unsung.

Every writer, from Milton, who mourned "How soon hath time the subtle thief of youth stolen on his wing my three and twentieth year" — to John Keats who had fears that "I will cease to be before my pen has gleaned my teeming brain," lives in the constant fear of dying before he has put on paper the immortal work he has it in him to write.

Authors, being nonconformists, are usually "agin" the government. England has always been harsh in her treatment of her greatest authors. Behind many a famous writer was a doctor who not only gave him professional care, but what was much more important . . . kindness and understanding when the author was in the agonies of creative composition or beset by the slings and arrows of outrageous fortune, shot by dull finished clods, untroubled by a spark.

William Makepeace Thackeray dedicated his novel to his friend and physician, Dr. Henry Thompson, whom he credited with saving his life.

When Samuel Taylor Coleridge exhausted his poetic gift by writing in ten months *The Rime of the Ancient Mariner* and *Christabel*, 1797-1798, he resorted to opium to alleviate the pains of frustration. Unable to control his addiction after ten years of degradation, he sought refuge with James

Flagyl destroys trichomonads

here & here & here & here

No topical treatment can

Flagyl®

brand of
metronidazole

Flagyl eliminates the difficulties and frustrations that have long attended the treatment of trichomonal infection.

These difficulties arose mainly from:

1) the failure of any previously known agent to destroy the protozoan in paravaginal crypts and glands;

2) the failure of any previously known agent to prevent reinfection by eradicating the disease in male consorts.

The introduction of Flagyl removed both of these long-standing deficiencies. Hundreds of published investigations in thousands of patients have confirmed the ability of Flagyl to cure trichomoniasis.

Correctly used, with due attention to repeat courses of treatment for resistant, deep-seated invasion and to the presumption of reinfection from male consorts, Flagyl has repeatedly produced a cure rate of up to 100 per cent in large series of patients.

Nothing cures trichomoniasis like Flagyl.

Dosage and Administration

In *women:* one 250-mg. oral tablet t.i.d. for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When the inserts are used one vaginal insert should be placed high in the vaginal vault each day for ten days, and concurrently two oral tablets should be taken daily.
In *men:* in whom trichomonads have been demonstrated, one 250-mg. oral tablet b.i.d. for ten days.

Contraindications

Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precautions and Side Effects

Complete blood cell counts should be made before and after therapy, especially if a second course is necessary.

Infrequent and minor side effects include: nausea, unpleasant taste, furry tongue, headache, darkened urine, diarrhea, dizziness, dryness of mouth or vagina, skin rash, dysuria, depression, insomnia, edema. Elimination of trichomonads may aggravate moniliasis.

Dosage Forms

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE
150 mg. CAPSULES

Effective in a wide range of everyday infections—respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Side effects typical of tetracyclines include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis, dermatitis, overgrowth of nonsusceptible organisms, tooth discoloration (if given during tooth formation) and increased intracranial pressure (in young infants). Also, very rarely, anaphylactoid reaction. Reduce dosage in impaired renal function. Because of reactions to artificial or natural sunlight (even from short exposure and at low dosage), patient should be warned to avoid direct exposure. Stop drug immediately at the first sign of adverse reaction. It should not be taken with high calcium drugs or food; and should not be taken less than one hour before, or two hours after meals.

Capsules, 150 mg. and 75 mg. of demethylchlortetracycline HCl.
Average Adult Daily Dosage: 150 mg. q.i.d. or 300 mg. b.i.d.

Influences of the University of Minnesota Upon the Wayne State University School of Medicine

Perhaps the most perilous and at the same time the most frequently undertaken literary assignment is to assess the influence of one person upon another. The peril is doubled when one tries to measure the effect of one institution upon another.

It would appear that the genetic lines of influence should be easy to follow in two universities and that in any two medical schools the task would be even more simple. However, medical schools are as complicated as the universities which nurture them. It would be logical that medical schools have much in common and that their objectives would be alike. Inasmuch as each does grant a degree, which after certain technicalities and a great deal of effort entitles the holder to practice his science and art, medical schools are very similar. The curricula are surprisingly alike but astoundingly dissimilar in their implementation. However, each seems to be a blend of strict scientific and scholastic discipline with a wide variety of human experience which has not been arranged in any very orderly way. It is this experience which permits the full flowering of human wisdom and the parallel development of convictions based upon empiricism.

The one unusual characteristic in the relationship of these two medical schools, Minnesota and Wayne State, is the relatively large number of faculty which have been drawn to the one from the other. The main flow has been from west to east. It is interesting that most of this faculty movement has taken place within the last thirty years.

Raymond B. Allen

It began with the appointment of Raymond B. Allen as Dean of Wayne State University School of Medicine in 1936. Dr. Allen was graduated from the University of Minnesota School of Medicine in 1928. During his three short years he brought to Detroit twelve faculty members, a number of whom were to influence the course of the Wayne State University School of Medicine. As might be expected, some of this group felt their institutional responsibilities keenly; others, to paraphrase Jacob Henle, looked upon the School as a "cow to be milked." Indeed, they behaved as any dozen men drawn at random from any population.

The influence of Raymond Allen and his energetic and skillful leadership mark a definite turning point in the affairs of the Wayne State University School of Medicine. He began the development of the full-time system in both preclinical and clinical departments. The importance of Allen's influence is difficult to overestimate. Firm and

On Stelazine® brand of trifluoperazine
she's calm and alert

When a tranquilizer is needed, 'Stelazine' can regulate the level of anxiety so that the patient is unlikely to overreact to stress but is not tranquilized into psychic inertia. Patients on 'Stelazine' often experience a sense of mental alertness and, because they feel so much better, are more interested in their normal activities.

Contraindicated in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose-related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems.

unwavering was his insistence that the faculty standards of Wayne be raised and that teaching in a medical school was an activity deserving the full attention of any faculty member. This was accomplished in an ambient medical opinion hostile to the development of a strong medical school. It was no mean feat.

His administrative abilities were quickly recognized by the University of Illinois. Before 1939 had ended, he was lured to Chicago to become Executive Dean of the Chicago Colleges of the University of Illinois. This was followed by his call to the presidency of the University of Washington, the Chancellorship of the University of California at Los Angeles, and to extremely sensitive and vital Federal Government posts.

In the years after Raymond B. Allen's deanship, his firm stands and sound administrative policies were challenged many times, but the directions of development were not reversed. Allen brought Edgar Norris (M.D., Minnesota, 1919) to Wayne State University in 1938, not realizing that he was to follow him in the decanal chair less than two years later. Norris presided over the affairs of the Medical School until February of 1945. From the beginning, his task was difficult. A part of this difficulty was the tremendous burden imposed by the times. The lack of proper facilities was an additional factor. Bruised egos and abraded sensibilities also made their contributions. These human qualities come to full flower in faculties, as in other groups, under the stress of overwork and wartime necessities.

Edgar Norris

In these war years, Edgar Norris was bold enough to undertake the planning of a medical center. The planning of such a group of medical activities was original and, on paper, not unlike a number of university medical centers now in existence. The plan stirred the interest of a number of influential Detroit citizens and in other times would have succeeded. It is sad, indeed, that it could not have been started with Dr. Norris to guide it. The importance of the adventure was that the medical center idea was put into the minds of Detroiters and is now in the stage of implementation. There have been many modifications; but the idea of gathering in one place the disciplines of medicine and of the paramedical sciences has now become an accepted way of undertaking the tremendously complicated and costly task of educating people in the health sciences.

Lawrence Berman and Gordon H. Scott

The influence on Wayne State's School of Medicine exerted by Edgar Norris did not end with his planning of a medical center. He brought twenty-two faculty members from Minnesota to Wayne in the five years he served as Dean. Among them is Lawrence Berman (M.D., 1937) who later served as Chairman of the Department of Pathology for three years and did much to further research programs in the School of Medicine. Just before Dr. Norris resigned as Dean, he offered the post of Chairman of Anatomy to the writer, who later served as acting Dean from 1948-50 and as Dean from 1950-63, and is now Vice President in Charge of Medical School Development.

It might be expected that Dr. Norris, being a pathologist, would have brought more pathologists from Minnesota than from other disciplines. This was not the case. During his five-year term, graduates of Minnesota were called to posts in internal medicide, pediatrics, surgery and several of its specialties. The effect was to strengthen, insofar as wartime permitted, the entire fabric of the School of Medicine at Wayne. Of the twenty-two Minnesota graduates brought by Dr. Norris, two became heads of important departments, Lawrence Berman in Pathology and Gordon H. Scott in Anatomy. Of the Minnesotans brought by Raymond Allen, two became heads of important departments, Edgar Norris in Pathology and James Lofstrom (M.D., 1932) in Radiology. Dr. Lofstrom served the school of Medicine for nearly 30 years and organized an effective department for teaching, research and service. Under his direction the first cobalt therapy equipment in the State was installed. He also was in charge of the linear accelerator installation — the first in Michigan.

**to help relieve pain
in common
anorectal disorders**

“non-caine”
Diothane®

Diothane—with its chemically distinct “non-caine” anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form... both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE
OINTMENT
CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Merrell

Allan Thal and Raymond Read

Another department head from Minnesota was appointed in 1961. Dr. Alan Thal did not take his medical degree from Minnesota but served as a faculty member, as did his colleague, Raymond Read. Dr. Thal is now chairman of the Department of Surgery and Read an Associate Professor of Surgery. They are at present developing an extensive program in open-heart surgery, distinctly reminiscent of some of the activities in Minneapolis, and in the fundamental aspects of shock.

Most of the faculty brought from Minnesota were full-time. A goodly number have stayed and are today holding appointments; others have left to assume faculty or research opportunities elsewhere, and some have gone into private practice. During the years since 1936, the University of Minnesota has sent more faculty people to Wayne State than any other one institution outside the State of Michigan. There is no doubt that the University of Minnesota has produced faculty members who have profoundly influenced the ultimate course of our Medical School. This is because a Minnesota graduate knows what a good University and a good medical school should be; it can also be credited to the experience and knowledge he brings to bear on his discipline: surely as good a base from which to develop a strong faculty as could be devised.

Gordon H. Scott, Ph.D.*
Detroit, Michigan

---

*Vice President for Medical School Development, Wayne State University.

Wayne State University and the Detroit Medical Center

THE NEEDS of the State of Michigan for more physicians have been ably documented and presented by several advisory groups whose studies have led to the recommendation that the School of Medicine at Wayne State University be expanded. This led to the decision to increase the entering class of medical students at Wayne from 125 to 200, and, perhaps ultimately, to 250. This increase will add the equivalent of another medical school in Michigan.

More than 10 years ago, a group of private citizens determined that Detroit must solve the grave problems confronting the major downtown hospitals because of the increasing spread of slums. The concept of a new Medical Center was developed, and the University with its medical school became a key part of the development. The School of Medicine at Wayne is unique in that it is the only medical school in a metropolitan area of about 4 million. The faculty is heavily involved in community service and community problems. These responsibilities are burdensome, but, as the Medical Center develops, they also represent a magnificent opportunity to relate medical education to the changing patterns of medical care.

The hard work, planning, and cooperative efforts of the past decade now find nearly 250 acres being cleared by the City of Detroit in downtown Detroit through urban renewal. This area is the site of the Detroit Medical Center, which is a complex of resources for teaching, research, patient care, and community service. This complex involves Wayne State University, the City of Detroit with its Detroit Receiving Hospital, the Federal government with a proposed new Veterans Administration Hospital, and private hospitals: namely, Harper, Grace, Children's, Woman's, and the Rehabilitation Institute. These private hospitals are planning extensive new construction, as well as renovation. A Medical Center organization is being developed between the University and these hospitals for the purpose of defining common goals relating to the teaching and research already being carried out in these private institutions.

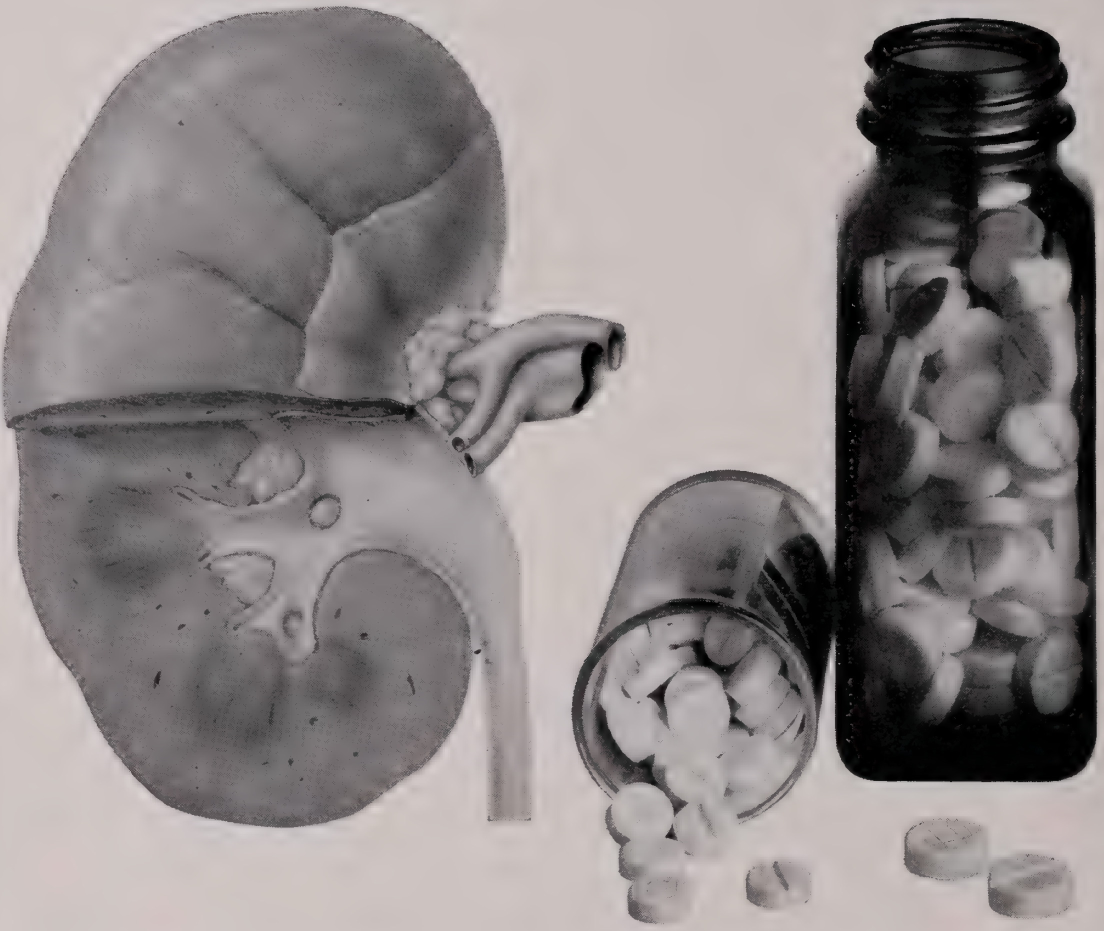
at Merck Sharp & Dohme...



understanding... precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

where today's theory is tomorrow's therapy

The University will have new research and instructional buildings in the Center which will enable it to accept more medical students. The first building, a 4-million-dollar research facility, has just been finished and is almost completely occupied. The teaching to be carried out in the Medical Center will include many different kinds of students. It cannot be emphasized often enough that modern, comprehensive health care involves much more than the physician, and that educational institutions concerned with health teach many more kinds of students than medical students.

We are engaged in an intensive study of our curriculum, because we realize that we have an extraordinary but short-lived opportunity, as the Center develops, to make those changes in medical education that are demanded by the changing pattern of medical care. Now in the years to come we will be dealing with a population which will be increasing dramatically. The increase is especially noticeable in the young and old groups. Furthermore, these people are concentrated in urban areas, and probably 20% make a major change of residence each year. Today, the major causes of death are due, not to infectious agents, but rather to cardiovascular disorders, neoplasms, and trauma. Because of these major changes, we must, by every means at our disposal, seek to instil in our medical students the idea of looking at each patient in terms of his family, environment, culture, and background or heredity, together with the natural history of the disease that he may have. We must make the student see that the acutely ill patient admitted to the hospital with an inflamed liver, for instance, is not just a "case" to be perfunctorily treated for his liver ailment alone and then arbitrarily released after a series of normal liver-function tests. The student must realize the importance of family, community, and socioeconomic factors in relation to health, and that treatment of symptomatic disease is but a part of the total picture of health care, which includes comprehensiveness and continuity.

A University by tradition is concerned with past, present, and future, and in keeping with this tradition a medical school must prepare students for tomorrow's medicine as well as for today's. I believe that the proper discharge of these traditional responsibilities by our faculty will ensure the success of the Medical Center. The University of Minnesota has a stake in this center because a significant number of our faculty have been drawn from the University of Minnesota. These men, who come from a medical school known for its high academic standard and strong University orientation, have been and continue to be a major influence on the developments at Wayne State University.

Ernest Gardner, M.D.
Detroit, Michigan

Detroit Receiving Hospital*

Its Relationship to the University of Minnesota Medical School and Medicine in Minnesota

DURING THE past 42 years many young graduates of the University of Minnesota Medical School have come to Detroit Receiving Hospital to intern. Some have come or have remained to serve residencies, and a few, already trained at Minnesota, have joined the staff of Detroit Receiving Hospital as members of the faculty of Wayne State University School of Medicine.

Dr. Raymond Read, who was graduated from the University of Minnesota Medical School and received his surgical training there, suggested that a description of this flux of young physicians from the University of Minnesota Medical School to Detroit Receiving Hospital be incorporated in this issue of "MINNESOTA MEDICINE."

Since 1923, one hundred and twenty-nine graduates of the University of Minnesota

Medical School have interned at Receiving Hospital. As might be suspected and as will be seen shortly, these numbers are too large to have been fortuitous.

Detroit Receiving Hospital, a municipal institution under the administration of the Welfare Department of the City of Detroit, was opened October 12, 1915, "to care for the sick poor of the City and others." New wings were added in 1921 and 1927 and on January 5, 1950, its administration was transferred from the Welfare Department to the Detroit Board of Health. In 1952 the eight-story air-conditioned Farwell Wing was completed and occupied.

There is neither need nor space for a review of the history of the University of Minnesota Medical School here, but it should be pointed out that from 1918 to 1952 the University of Minnesota granted the Bachelor of Medicine (M.B.) degree on graduation and the Doctor of Medicine (M.D.) degree following completion of the required internship. In 1953 this was changed back to the original system in operation prior to 1918, in which the M.D. degree was awarded upon graduation.

Jennings C. Litzenberg, Professor and Head of the Department of Obstetrics and Gynecology at the University of Minnesota from 1914-38 and Chairman of the Intern Committee for most of the period, was responsible for the link between the University of Minnesota Medical School and Receiving Hospital. When an internship became a requirement for the M.D. degree at the University of Minnesota, the Intern Committee then proceeded to classify hospitals according to their assessment of these hospitals' educational value for interns. Dr. Litzenberg visited many hospitals and sent out many questionnaires. Supplemental information was obtained from confidential sources. During this period hospital superintendents or chiefs of staff were required to report in detail twice yearly upon the performance of Minnesota interns; and in turn the interns were required to report similarly as to the quality of teaching they received, the responsibility given them, the quality of patient care and the standards of performance demanded of them. The reports of these graduates on the hospitals in which they interned were available to Minnesota seniors in the office of the Intern Committee. During this period the Intern Committee actually supplied internships for those graduating from the University of Minnesota Medical School. The Intern Committee agreed to supply a given number of interns to a given hospital, and that hospital in turn agreed to reserve this number of internships for the Minnesota graduates named by the Committee.

Each senior would list his choices in order of his preference from the list of approved hospitals, and whether or not he obtained his first choice depended upon his class standing. For many years three to five graduates ranking near the top of their class at Minnesota came to Receiving Hospital to intern. This system changed after the war and now has been replaced by the National Intern Matching Plan.

Of the 141 graduates of the University of Minnesota Medical School who came to Detroit Receiving Hospital in one capacity or another (129 as interns), five are deceased; two are retired and nine others are not shown in the 1963 Directory of the American Medical Association. Fifty returned to Minnesota to practice, twenty-two remained in Michigan and fifty-one were practicing in other states in 1963. The achievements of these physicians have been outstanding. In 1963, 73 were certified specialists, and 18 were specialists without certification. Forty-two were members of medical school faculties. Thirty of these were voluntary faculty members. Twelve were or had been full-time faculty members. Five of these were full professors (two were departmental chairmen and two had been chairmen of departments). On the present staff of Receiving Hospital there are five of professorial rank: Dr. James Lofstrom, Professor of Radiology, Dr. Alan Thal, Professor and Chairman of Surgery, Dr. Lawrence Berman, Professor of Pathology, Dr. Raymond Read and Dr. Ernest Berkas, Associate Professors of Surgery.

Dr. Wendell Hall, after interning at Detroit Receiving Hospital, returned to Minneapolis

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

WALLACE LABORATORIES
Cranbury, N.J.

CM-9781

to continue his training in internal medicine and is currently Professor of Medicine and Head of the Medical Department at Minneapolis Veterans Hospital.

Two others have had distinguished military medical careers. Captain John S. Cowan, M.C. USN, an internist, is currently commandant of the Philadelphia Naval Hospital. Prior to this he was Director of Medical Affairs (Supreme Allied Commander NATO) and Fleet Medical Officer (U.S. Atlantic Fleet, Norfolk). Colonel Robert J. Kamish M.C. USA, a surgeon, was chief of Surgery at Gorgas General Hospital and had been Chief Surgical Consultant (Europe) 1956-58 and chief of Professional Services at Letterman General Hospital 1960-62.

If space permitted, many other distinguished careers could be recounted, for many other men have come to occupy positions of distinction in their specialties throughout the Midwest and the West. It is apparent that the relationship between these two institutions has been a fruitful one. While it has benefited medicine most in Minnesota and Michigan, its effect has been felt throughout the United States.

Muir Clapper, M.D.
Detroit, Michigan

I should like to express my thanks for the generous help given me by Mrs. Edith A. Lindberg, formerly Secretary to the late Jennings C. Litzenberg, M.D., by H. Mead Cavert, M.D., Associate Dean, The University of Minnesota Medical School and by Donald B. Frane, M.D., all of Minneapolis.

Air Pollution and Health*

THE TUBE bridges a busy street in downtown Detroit. Five to ten thousand cubic feet per minute of street air is drawn through the tube and delivered into an adjacent laboratory. In that location a number of automatic systems constantly monitor the quality and quantity of eight different constituents. Animals exposed to the intake air are under study in order to assay their physiologic, anatomic and biochemical responses. The air we breathe, in relation to occupational and nonoccupational situations, may contain a variety of pollutants which have toxic effects; accordingly they have the capacity to induce disease in strategic segments of the respiratory tract and lung. In addition, certain inhaled pollutants are absorbed from the lung and thus may provoke a variety of functional and structural changes in nonpulmonary tissues and organs of the body, the nature and extent of the adverse effects depending upon a number of variable factors. From the physical viewpoint, the pollutant may occur in the form of dust, fume, mist, vapor or gas. Although much is still to be learned about pollutants, the air in most highly industrialized urban situations usually includes a large number of inorganic compounds having components which range from aluminum to zinc in the alphabetic list of elements. Among the common gaseous pollutants there may be excessive concentrations of carbon monoxide, nitrogen oxides, sulfur oxides, aldehydes, hydrocarbons, chlorides and fluorides. Oxidants also occur, and in the presence of sunlight they may react with other pollutants to form new compounds. Radioactive substances may comprise a considerable portion of a polluted atmosphere. Pertinent examples include gases and vapors created by chemical processes, gases and fumes in foundry situations, mists and vapors in spraying operations, dusts and fumes of mineral substances generated by uncontrolled mining, milling and processing operations, dusts of demolition

The tell-tale lesion on the back of her neck

ARISTOCORT Topicals are particularly effective in controlling the inflammatory symptoms of many dermatoses including neurodermatitis, atopic dermatitis, eczematous dermatitis, seborrheic dermatitis and certain cases of psoriasis. The 0.1% Cream or Ointment is usually effective in abating symptoms of skin conditions responsive to topical triamcinolone, but the 0.5% Cream may be preferable in more resistant cases. *Dosage:* Apply small quantity to area 3 or 4 times daily. Side effects are rare. *Contraindications:* tuberculosis of the skin, herpes simplex, chickenpox, and vaccinia. Use with care on infected areas. Do not use in the eyes. Supplied in 5 and 15 Gm. tubes and ½ lb. jars. Also available in foam form and with Neomycin.

work, and last but not least the products entrained in vehicular exhausts and stack effluents.

The physical nature of the airborne pollutants, especially in regard to their mass (total weight), shape and size, determine in large measure whether or not the particulates remain suspended in the atmosphere and can then pass the defense barriers of the respiratory tract and gain entrance into the finer airways and alveoli of the lungs.

It is generally recognized that particle size has an inverse relationship to its ease of entrance into the bronchopulmonary system. The real issue, however, concerns the point of declining size at which the inverse relationship may cease to exist. Resolution of that issue is difficult pending more precise knowledge concerning the number of ultramicroscopic particles in the inhaled air and the kinetic properties of those particles, especially in relation to their penetration, primary deposition, retention and transport in the airways and lungs. Concentration of the pollutant in the inhaled air is an exceedingly important factor which operates to govern the amount that is brought into contact with the target tissue. The tolerable atmospheric concentration of many pollutants has been prescribed in terms of safe threshold values (MAC: maximum acceptable concentration) which should not be exceeded in occupational situations, if the adult and relatively healthy exposed employee, working approximately eight hours daily, is to remain free of occupational respiratory disease. Those values, however, must be cautiously applied to community air which involves a potentially continuous twenty-four-hour exposure of a population which includes the very young and the very old, the healthy and the sick, the resistant and the highly sensitive individual.

One of those variables which influence the nature and extent of the biologic damage to tissues, concerns the duration of the exposure, viz., whether it is brief or prolonged, continuous or intermittent. Within certain limits, brief or intermittent exposures to extreme amounts of a pollutant are capable of producing acute damage, which may either resolve or leave in its wake a series of subtle and gradually developing chronic effects. Similar effects may result from prolonged or continuous exposure to low atmospheric levels of certain pollutants. In regard to effects, it should be recognized that not all pollutants are intrinsically toxic. Some are relatively inert and nontoxic, whereas others, either alone or in combination, are biologically active and toxic. Not all persons react alike; some are partially or almost completely resistant, whereas others are unduly susceptible and respond early with subjective and objective deviations from the norm.

In final analysis, the toxic effects of inhaled atmospheric pollutants are determined by an interplay between the competing forces inherent in the pollutant per se and in the exposed person, especially the older individual who may have structural and functional impairment unrelated to his inhalation of an atmospheric pollutant.

Aneurysmal Abscess

MYCOTIC ANEURYSMS* occurring as secondary complications of septicemia have been recognized since their first description by Osler in 1885. Infection and destruction of an adjacent arterial wall by a necrotizing abscess likewise, has been appreciated for more than a century. However, Huebl and Read, in their paper, "Aneurysmal Abscess,"** describe two new etiological modalities, iatrogenic and egogenic.

Two of their cases, iatrogenic in origin,

Butazolidin® alka

phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

Usually works within 3 to 4 days in osteoarthritis

The trial period need not exceed 1 week. In contrast, the recommended trial period for indomethacin is *at least 1 month.*

That's why it's logical to start therapy with Butazolidin alka—you'll know quickly whether or not it works. And usually, it will.

A large number of investigators have reported major improvement in about 75% of cases. Some patients have gone into remission. Relief of stiffness and pain may be followed quickly by improved function and resolution of other signs of inflammation. And Butazolidin alka is well tolerated, especially since it contains antacids and an antispasmodic to minimize gastric upset.

Contraindications
Edema, danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile, or when other potent drugs are given concurrently. Large doses are contraindicated in patients with glaucoma.

Precautions
Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Make regular blood counts. Use greater care in the elderly.

Warning
If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy.

Adverse Reactions
The most common are nausea, edema and drug rash. Hemodilution may cause moderate fall in red cell count. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Dosage
The initial daily dosage in adults is 300-600 mg. daily in divided doses. In most instances, 400 mg. daily is sufficient. When improvement occurs, dosage should be decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

Also available: Butazolidin®,
brand of phenylbutazone
Tablets of 100 mg.

Geigy Pharmaceuticals

followed carotid angiography done by direct needle puncture of the carotid arteries. Both cases developed paravascular staphylococcal infected hematomas which destroyed the arterial wall. The other two cases, egogenic in origin, followed habitual intrafemoral vein self-injection of paregoric by addicts. Inevitable spillage of this necrotizing camphor compound into the paravascular tissues of the femoral artery produced abscesses which destroyed the arterial wall. Aneurysmal abscess resulted in all four cases.

These authors describe the bold surgical intervention required to drain these abscesses and to control the vascular disruption and the lifesaving surgery. They also describe the extremities which result.

It would seem prevention is the only hope if no cure exists. Direct needle puncture of an artery is always hazardous. Perhaps needling of the carotids is not the best method of opacification for angiography. Arch injections by a catheter introduced into the ascending aorta through a right brachial arteriotomy provides more information by opacifing the origin and course of both vertebral and carotid arteries while avoiding injury to these crucial vessels. Open arteriotomy and proper repair assures patency of this vessel and eliminates the hazards of hematoma and tissue injection inherent in blind needling.

Arch injection requires sophisticated rapid film-changing devices providing serial films of the progress of the opacifying medium, but this, in turn, gives information regarding flow rates as well as luminal diameters.

Intravenous self-injection of paregoric does not seem to be the best way to handle the addiction problem. The human agony of these two case reports cries for a better solution. Iatrogenic aneurysmal abscesses can be avoided by a better method of carotid and vertebral angiography than blind needling of these major arteries for contrast injection. Egogenic aneurysmal abscesses illume the agony of addiction and urge a better understanding of human dependency.

Pyoderma Gangrenosum*

PYODERMA GANGRENOSUM is a well-established clinical entity consisting of noninfectious furunculoid lesions of the skin which rapidly break down and form ulcers that spread peripherally. Healing usually begins centrally in the lesions, and the scar, which is likened to the texture of cigarette paper, is characteristically soft and noncontractile. The clinical appearance of the lesions is distinctive, but occasionally the ulcers may be confused with those due to tuberculous, deep mycotic, or pyogenic organisms and to hypersensitivity to bromide or iodides.

Experience at the Mayo Clinic has shown that chronic ulcerative colitis is an associated finding in approximately 50% of cases involving pyoderma gangrenosum. Rheumatoid arthritis and rarely a vesicular eruption simulating dermatitis herpetiformis** may be present. The clinical course of the skin lesions is a chronic relapsing one, lasting several months or years, and spontaneous flares and remissions of the ulcerations are not uncommon.

The key to the treatment of pyoderma gangrenosum lies in the general health of the patient, particularly in the control of the chronic ulcerative colitis when present. My colleagues and I have found that the most useful drugs are sulfapyridine, sulfone derivatives, and oral corticosteroids. The choice of drug depends on the individual's response to therapy. Some patients with pyoderma gangrenosum are responsive to sulfapyridine but resistant to sulfones and vice versa. Also,

"All Interns are Alike"

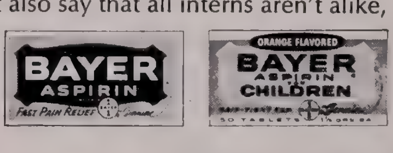
It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.



unusually large necrotic lesions may heal only with large doses of corticosteroids, and such therapy may be lifesaving. At times, the administration of these drugs in combination, at reduced dosages, will effect better suppression of the disease and result in fewer complications from the drugs.

The two cases reported on by Altman and Mopper in this issue of MINNESOTA MEDICINE are examples of effective control of the disease by sulfones, although the presence of pyoderma gangrenosum is questionable in the second case.

The mode of action of sulfapyridine and sulfone in the control of pyoderma gangrenosum is not known. These drugs also are effective in the suppression of various noninfectious skin disorders such as dermatitis herpetiformis, subcorneal pustulosis, Weber-Christian disease, and acrodermatitis continua. Lorincz and Pearson have postulated that sulfapyridine, sulfones, and related drugs exert a therapeutic effect by combining or reacting with tissue or bacterial polysaccharides. Whatever the mechanism of effect, the therapeutic value and the requirement for maintenance doses of these drugs for long periods pose the problem of potentially serious side effects from these drugs. While generally less toxic, diaminodiphenylsulfone (Avlosulfon) is usually less effective than sulfapyridine. Notwithstanding its potential toxicity, sulfapyridine is the drug of choice for the majority of patients.

The Carcinoid Syndrome

THE REPORT by Zobl et al.* in this issue, concerning the circulatory and cardiac manifestations of malignant carcinoids, presents further data about this remarkable experiment of nature which has given us insight into metabolic, morphologic and clinical problems.

Cassidy described the first clearly recognizable example of this fascinating syndrome in 1930, but it remained only as a curiosity because of lack of a physiologic or anatomical background to which it could be related. In a quarter of a century the studies of Ersparmer on the enterochromaffin system of invertebrates; Rappoport's studies on serum vasoconstrictor (serotonin); Lembeck's isolation of serotonin from an intestinal carcinoid, and Barter and Pearse's demonstration that the granules of the Kulschitsky or enterochromaffin cells of vertebrate small intestine contained a serotoninformaldehyde complex made possible the remarkable synthesizing hypothesis of Thorson et al., in 1954, that serotonin, chemically 5-hydroxy tryptamine, produced the anatomical changes and clinical symptoms of patients with metastasizing carcinoids. When in 1955, Waldenstrom and Ljungberg demonstrated high serum serotonin levels in patients with the carcinoid syndrome, this hypothesis seemed almost proven.

Data have accumulated from about 200 reported cases of the syndrome. Most originated from primary small intestine tumors, but about two dozen were of bronchial origin and some arose from carcinoids in ovarian or testicular teratomas. The early indications that excess serotonin secretion would fully explain the syndrome have faded. Such modifications of the original hypothesis that only free rather than total serum serotonin was active; that factors involving release of serotonin were important; that the site of metastasis was a determinant or that variations in the amount of pulmonary monoamine oxidase, deaminating serotonin, were significant, have not sufficed. One of the strongest objections to the simple serotonin hypothesis has been the failure of numerous investigators to produce experimentally the characteristic heart valve lesions.

GROUND BROKEN!
NOV. 17, 1965
APACHE

APACHE PLAZA MEDICAL COMPLEX

"Standing in the middle of a boomtown in the North . . . in the middle of a 'doctor-poor' area"— *Mayor James McNulty, St. Anthony Village, in a speech at the ground-breaking ceremony for Apache Plaza Medical Complex, November 17, 1965.*

You're right, Mayor McNulty. That's why Apache Corporation's Real Estate Division decided to build a medical complex at Apache Plaza.

We knew the statistics. While the five-county metropolitan area population was growing 13.8 per cent from 1960 to 1965, the population in the area served by Apache Plaza grew 47 per cent.

We knew the Apache Plaza area statistics on doctors, too—one g.p. for each 4,100 people, one ob-gyn for each 21,000 persons, and one pediatrician for each 17,000. And we knew that there weren't enough doctors—because our customers told us many times that the small medical facility we now have just wasn't big enough. We know another thing—the growth in this "boomtown" area, northeast of Minneapolis and northwest of St. Paul, is going to continue.

Doctors are needed. And Apache is going to offer doctors the finest medical facility in the Upper Midwest. So, Doctor, if you'd like to practice in boomtown, in a modern medical building with ample parking, pathology and radiology labs, essential ancillary services, and totally flexible space-planning, call or write:

Evidence has accumulated to indicate that the argentaffin* or enterochromaffin cells and carcinoid tumors derived from them contain substances other than serotonin that may be involved in producing the syndrome. Catecholamines (adrenalin and noradrenalin), histamine and serotonin analogues have been demonstrated in the tumors and in serum, and their implication in the syndrome suggested. Ascorbic acid has also been demonstrated in the tumors. The work of Oates et al., suggesting that carcinoids contain undefined substances which may activate kinins to form bradykinin, and the histochemical studies of Lillie and Glenner indicating the presence of ill-defined lipids and other substances in the cells of carcinoid tumors, give promising leads. Electron microscopy has demonstrated a distinctive appearance with neurosecretory granules resembling those of neuroblastoma and paraganglia. An adequate synthesis of these interesting possibilities is still to be made.

A number of uncommon associations of the carcinoid syndrome are intriguing. They include other endocrine abnormalities such as acromegaly, Cushing's syndrome, hypoglycemia, parathyroid adenomas and the pluriglandular adenomatosis syndrome. Most of these involve bronchial rather than intestinal carcinoids. Reports of oat-cell carcinomas secreting serotinin or associated with the carcinoid syndrome indicate that some bronchogenic carcinomas may be undifferentiated carcinoids.

It is evident that many permutations and combinations of this experiment of nature will be observed in the future. Investigation in depth by sophisticated modern techniques may unfold new chapters in physiology, pharmacology, anatomy and clinical medicine.

**Director of Laboratory, Mount Sinai Hospital.

Letter to the Editor:

Two deaths are reported under regional block anesthesia.* During my ten years with Dr. R. E. Farr and the many years that I used local anesthesia, we made it mandatory that when the point of the needle was stationary, the plunger of the syringe should be aspirated in order to be sure that the needle point was not in a vein; also, the needle was kept in motion. This is particularly imperative in the region of the board ligament where large veins are abundant. Though the quantity of the drug used is of great importance, far more important is the technique of its injection. We found by experimentation in animals that the intravenous injection of procaine is most hazardous, but that, in our experience, procaine was adequate and safe when properly used. I have had no experience with Cyclaine or Xylocaine.

I recall an operation on a foot by Dr. Farr under intravenous novocain anesthesia with a tourniquet control. The patient immediately showed toxic symptoms which stopped at once when the tourniquet was adequately tightened.

I compliment Drs. Freeman, Barno, and Baken on an excellent and important contribution.

The Hippocratic Horoscope

When Hippocrates was called in on a medical case, he immediately had a horoscope drawn up for his patient's disease. This wheel, representing the stellar sphere, was sectioned into eight equal 45-degree triangular 'houses'; and on it, by accurate sidereal calculation derived from an ephemeris, were charted the sun, moon, and planets. Then from their relative configuration Hippocrates calculated the course of the disease from its inception through its crisis (or crises) to its termination; from this horological perspective he deduced what method of treatment to adopt. If the disease continued longer than one lunar cycle, he regarded it as no longer acute but as chronic, and therefore as requiring a new wheel. Hippocrates relied on horoscopes!

If children grew up according to early indications, we should have nothing but geniuses. — Goethe

The Editor's Soliloquy

Etiology? — Physiologic!

Throughout medical history doctors have learned to treat diseases and their attendant symptoms long before the etiologic factors have become apparent. In the prescientific era the roster of suspected factors included enemy hexes and divine retribution; the phases of the moon and the conjunction of the planets; night air and swamp miasma; and more latterly, Grandfather's unabsolved sins.

Even in this supposedly myth-emancipated era of the Twentieth Century patients still continue to probe for causes. Before consulting their physician, they have inculpated some one event or constellation of events to account for their symptoms; they are reluctant to abandon their delusions and to accept academic explanations involving the complexities of pathologic anatomy, biochemical imbalances, embryological aberrations, congenital defects, and a host of other phenomena.

When confronted with irrefutable evidence that what she has is arthritis in the spine, sugar in the urine, cholesterol in the blood, or a tumor in the breast, is the female patient willing to accept physiologic malfunction as a cause? No indeed! She never had that before and is sure she doesn't have it now. Besides, she can't recall anything that could have produced such a sinister visitation!

There are many disorders and diseases for which we know no specific cause. Why do we grow old in body when our spirit remains young? Why does our hair turn gray and lusterless; why do we develop excrescences on our joints and on our vertebrae, keratoses on our back and pinpoint papilloma on our neck; why do we lose spots of pigment on our skin? Why are we stiff in the morning when we arise, when we work too hard, when we sit too long? Why does our neck or back ache after washing the ceiling, after ironing all morning, after driving the car for long distances? Why, after forty, does our blood pressure go up, our heart beat too fast, our hearing diminish, our vision shift, our gums recede, and our joints creak?

Why can't we keep the natural color and sheen of our hair, the petal freshness of our skin, the litheness of our body, the spring in our walk, the vibrancy in our voice, the stars in our eyes?

Why? — Let's face it! Inexorable physiologic age is catching up with us. Do we flout the idea of moderation: grow fat, get out of physical trim, do everything in excess? Is it not sufficient to know that burning the candle at both ends speeds up our physiologic time clock; and that these manifestations are not caused by an event, an incident; and that there may be no one but ourselves to blame — or to sue!

Carl O. Rice, M.D.

Mom says: It's nice to get up in the morning because your troubles haven't had time to get started.

The Mouse Amulet

For six thousand years the mouse has figured in medicine.

When, after the annual spring floods in ancient Egypt, the people saw mice emerging from the silt cracks of the fresh Nile deposit, they naively concluded that since the perennially revitalized soil produced the fresh crops on which they relied for sustenance, the mouse must incarnate the universal life principle, and hence that human consumption or application of the animal would transmit that vital force from mouse to man: a rational deduction from a fallacious premise.

Skinned, cooked, and eaten the mouse was apparently employed as a last desperate resort in terminal illness — especially for children in extremis. Ancient cemeteries in Egypt have yielded children's corpses — intact because of the dry sand in which they were interred — the stomachs and alimentary canals of which contained the remains of mice. Later scientific investigations have verified the practice in other areas of the East and in parts of Europe.

In Pliny's era also the belief prevailed that the mouse derived spontaneously from the Nile mud after each fresh inundation and was therefore a life-giver and a life-saver. Both Dioscorides of Greece and Abd er-Razzak of Algeria solemnly alleged that the ingestion of roasted mice would stop dribbling at the mouth in children, besides being a specific both internally and externally for multifarious ailments — from incontinence to warts.

The numerous papyri so ably translated by experts corroborate the therapeutic virtues of the "wee beastie." The Ebers Papyrus (1550 B.C.) prescribes mouse fat mixed with other miscellaneous fats for rheumatism. For healthier hair and to combat alopecia the Hearst Medical Papyrus suggests anointing the head with cooked mouse that has been allowed to rot in a mess of fat. The Erman Papyrus (1500 B.C.) advises that when a child is sick, either he or his mother eat a mouse and that the child then wear around his neck the bones of the same mouse bound together with a string in which seven knots have been tied.

For ulcers the Coptic Papyrus (800-900 A.D.) advocates a concoction of one ounce each of wax, santal,* pig lard, and chopped up mouse — all cooked together. Culpeper (1659) advised a three-day dose of powdered mouse for diabetics and those unable to hold their water.

Finally, in the Pharmacopoeia Universalis of one Dr. R. James, M.D. (1752), we are more fully apprised of the astonishing therapeutic versatility of the lowly mouse. "The whole Animal, and its Dung are used in Medicine. The Mouse, cut up alive, and applied, draws out Splinters, Darts, and Arrows, and cures the Bites of Scorpions, extracting the Poison. The Ashes cure the involuntary or nocturnal Flux of the Urine. The Dung purges Infants by Stool, is used in Clysters, cures an Alopecia, absterges Scurf from the Head, diminishes Stones in the Kidneys, or Bladder, and removes a Condyloma, Verruca, Ficus, Marisca, and the Tumors affecting the Anus."** Just like that!

The mouse myth persisted right up into the first quarter of the Twentieth Century in England and Wales, where flayed, fried, boiled or baked in a pie, the mouse was still relied upon to cure whooping cough, dribbling at

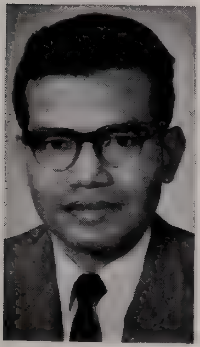
Our Contributors

. . . . from

Wayne State University
Detroit, Michigan

Jules Altman, M.D.

Dr. Jules Altman, born and educated in Europe, graduated from the University of Minnesota in 1958 where he interned. He trained at the Mayo Clinic in dermatology and is at present an instructor at Wayne.



Agustin Arbulu, M.D.

Dr. Agustin Arbulu was born in Lima, Peru, educated at San Marcus University, Lima, and received residency training in the United States in surgery. He is now Assistant Professor of Surgery at the Veterans Hospital, Dearborn, and is an instructor in the Department of Surgery at Wayne State.

Ernest Berkas, M.D.

Dr. Ernest Berkas, born in North Dakota, graduated from the Univesity of Minnesota in 1951, interned at St. Joseph in St. Paul. He completed his general surgical residency at Minneapolis Veterans Hospital and is Chief of Surgery at the Veterans Hospital in Dearborn and Associate Professor in the Department of Surgery at Wayne State.

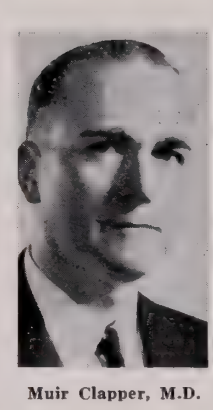
Continued

Richard Bing, M.D.

Dr. Richard Bing, born and educated in Europe, interned with Presbyterian Hospital, New York, and was a resident at Johns Hopkins. He joined the staff and left to be Professor of Medicine at Alabama, Washington University, St. Louis, and then departmental chairman at Wayne. He has lectured and published extensively on cardiac metabolism.

Jacob Chason, M.D.

Dr. Jacob Chason was born and educated in Michigan. He graduated in 1940 from Ann Arbor and received his pathological training in Michigan and at the Mayo Clinic. He is now acting Chairman of our Department of Pathology.



Muir Clapper, M.D.

Dr. Muir Clapper was born in Detroit, educated at Wayne State and received his graduate training in medicine at Receiving Hospital. He is now professor of medicine and has made a number of distinguished contributions to cardiology.

Alberto Cohen, M.D.

Dr. Alberto Cohen was born in Rio De Janeiro, educated in Brazil and is now in cardiovascular physiology at Wayne State University.

Dr. Ernest Gardner, born in the state of Washington and educated at their university, graduated from Stanford Medical School in 1941. He went into anatomy after his internship and became chairman of the department at Wayne in 1950. He is at present Dean of the Medical School and is the editor of a number of texts in anatomy as well as research papers concerning various aspects of connective tissue, bones and joints.

Ernest Gardner, M.D.

Dr. Paul Gonick was born and educated in New York. He received his M.D. from Yale in 1955 and was a resident at the Veterans and University Hospitals in Minneapolis in general surgery and urology. He is now chief of the section at Veterans Hospital in Dearborn and instructor at Wayne State. He has been interested in transplantation.

Paul Gonick, M.D.

Dr. Hubert Huebl was born in Montana, educated at the University of Chicago and Washington University, St. Louis, where he graduated M.D. in 1956. He interned at the Minneapolis General Hospital and was resident in Surgery first at Bellevue and then at Detroit Receiving Hospital. He is now an instructor in the Department of Surgery at Wayne State.

Hubert Huebl, M.D.

Dr. Alan Hymes, born in Minneapolis, graduated from the University of Minnesota Medical School in 1956, interned at Kings County, Brooklyn. He received his residency training at the Minneapolis Veterans Hospital in Surgery and is now a clinical investigator at the Dearborn Veterans Hospital studying cardiopulmonary bypass.

Alan Hymes, M.D.

Gordon Scott, Ph.D.

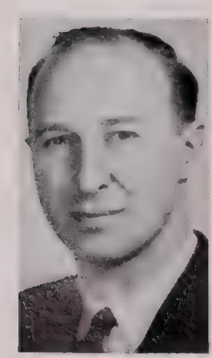
Dr. Gordon Scott, M.A. 1925, Ph.D. 1926, Minnesota, worked at Loyola, Rockefeller Institute, Washington, University of St. Louis and then was appointed chairman of the Department of Anatomy, University of Southern California in 1942. He came to Wayne in 1945 and was its Dean from 1950-1963. He is now Vice President for Medical College Development. He performed pioneering studies in the application of the electron microscope to medical research.

Walter Seegers, Ph.D.

Dr. Walter Seegers, born in Iowa, graduated from State University, Ph.D. 1934. He came to Wayne in the Department of Physiology in 1945, became chairman in 1946. He has received many distinctions and has published widely in the field of blood coagulation.

Allen Silbergleit, M.D.

Dr. Allen Silbergleit, born in Massachusetts, graduated from the University of Cincinnati Medical School in 1955, interned at the University of Minnesota. He was a resident in surgery at the Veterans Hospital, Minneapolis, and is now an instructor in surgery at Wayne State University.



Alan Thal, M.D.

Dr. Alan Thal, Chairman of the Department of Surgery, Wayne State University School of Medicine, received his surgical training under Dr. Wangensteen at the University of Minnesota 1952 to 1957, later joining the staff. He made distinguished contributions in the field of surgical sepsis, pancreatitis, and cardiovascular disease. He has recently developed an outstanding shock unit.

Dr. Arthur Vorwald was born in Dubuque, Iowa, where his father practiced. He was educated at the University of Chicago and Cambridge University, England, and has attained an international reputation in pulmonary pathology and problems connected with dust inhalation.

Arthur Vorwald, Ph.D., M.D.

Dr. Alexander Walt was brought up in South Africa and received his surgical training at the Mayo Clinic. He is Associate Professor of Surgery at Wayne, and Assistant Dean.

Alexander Walt, M.D.

Dr. Edward Zaleski, born and educated in Pennsylvania, graduated from Wayne State in 1959. He interned and was a resident in the Department of Medicine at Receiving Hospital. He is now an instructor with Dr. Bing.

Edward Zaleski, M.D.

Dr. Eldred Zobl, born and educated in Detroit, graduated from Wayne in 1954. He is chief of the cardiac catheterization laboratory at the Veterans Hospital in Dearborn and is interested in problems of cardiology.

Eldred Zobl, M.D.

Curbstone Consultation

Ulcerative Colitis

QUESTION: In a patient who has suffered symptoms of ulcerative colitis for five years, with both X ray and proctoscopic evidence of the disease, would you recommend topical steroid treatment?

ANSWER: Although our experience indicates that 30% of patients with ulcerative colitis for five years or longer will not respond to this therapy, 60% of patients did respond and the majority of those responding did so both clinically and proctoscopically. Furthermore, when response occurs it is generally prompt. If no response was apparent in a week, I would add systemic steroid (preferably ACTH intravenously). If no response occurred within this week, I would stop the topical steroid. If the patient was acutely or desperately ill, I would begin therapy with topical and systemic steroids.

Fogging

QUESTION: Under the usual circumstances of mosquito control by the practice of fogging, is there sufficient danger of causing toxic effects to eliminate this practice?

ANSWER: Fogging for mosquito control does not result in any known hazard to health as the procedure is usually performed. The exposure is usually relatively brief. It may be a nuisance to those exposed to the insecticide but this nuisance must be weighed against the nuisance of the mosquitoes. An occasional person may have an adverse reaction to the spray procedure. This reaction may be somatic or functional and the differentiation may prove difficult. As a general rule, unnecessary exposure to pesticides should be kept to a minimum but the definition of "unnecessary" is one that cannot be decided without careful appraisal of the reason for the use of the insecticide.

The Doctor and Literature

(Continued from page 73.)

Gillman, a physician at Highgate in 1816. Coleridge remained under the supervision of the understanding doctor until 1834. In those years, he wrote his finest literary criticism.

Today, many an ambitious man hires a Madison Avenue public relations expert to project a favorable image of himself to the public. Whether the socially acceptable image corresponds to the real man is immaterial.

The criticism levelled by Chaucer at the doctor of physik, by Shakespeare at the apothecary, and by Henry Fielding at the leech, so-called because the Eighteenth Century Doctor used those repellent creatures to suck infected blood from a patient, is not always favorable.

Hogarth, the Eighteenth Century Cartoonist, in a savage cartoon; *The Consultation of Physicians,* depicts twelve doctors with voluminous white wigs and gold-headed canes peering interestedly into the contents of a urinal. Hogarth believed most of the doctors of his time were quacks.

A Novel

A novel is a prose narrative of considerable length, which has plot, setting and characters. Novels of plot emphasize action; in them the characters are subsidiary to the working out of the action to a conclusion. An Agatha Christi "whodunit" has characters involved in the crime which is solved in the last chapter.

Any novel of prison life, whether Dostoevski's *House of the Dead* to Jerome Odlum's *Each Dawn I Die,* based on his imprisonment at Stillwater penitentiary, has only one plot: a prisoner does not like where he is and wants out.

In novels of character, the people in the story predominate over the plot which is frequently negligible. The Fat Boy in *Pickwick Papers,* Sherlock Holmes, Scarlett O'Hara, James Bond, 007 are more real to us than our next door neighbors; but the plots of the novels in which they appear are quickly forgotten.

Lizardry

Marcellus (5th century A.D.) advises: To stay colic one binds about the patient three times with an incantation a string with which a copper needle has been threaded and drawn through a (green) lizard's eyes, after which the reptile is released at the same point where it was captured.

In another passage Marcellus recommends the drawing by a silver needle of threads of nine different colors other than black or white through the eyes of a new-born puppy before they open, after which the puppy is to be thrown into the river.*

X-ray Conference

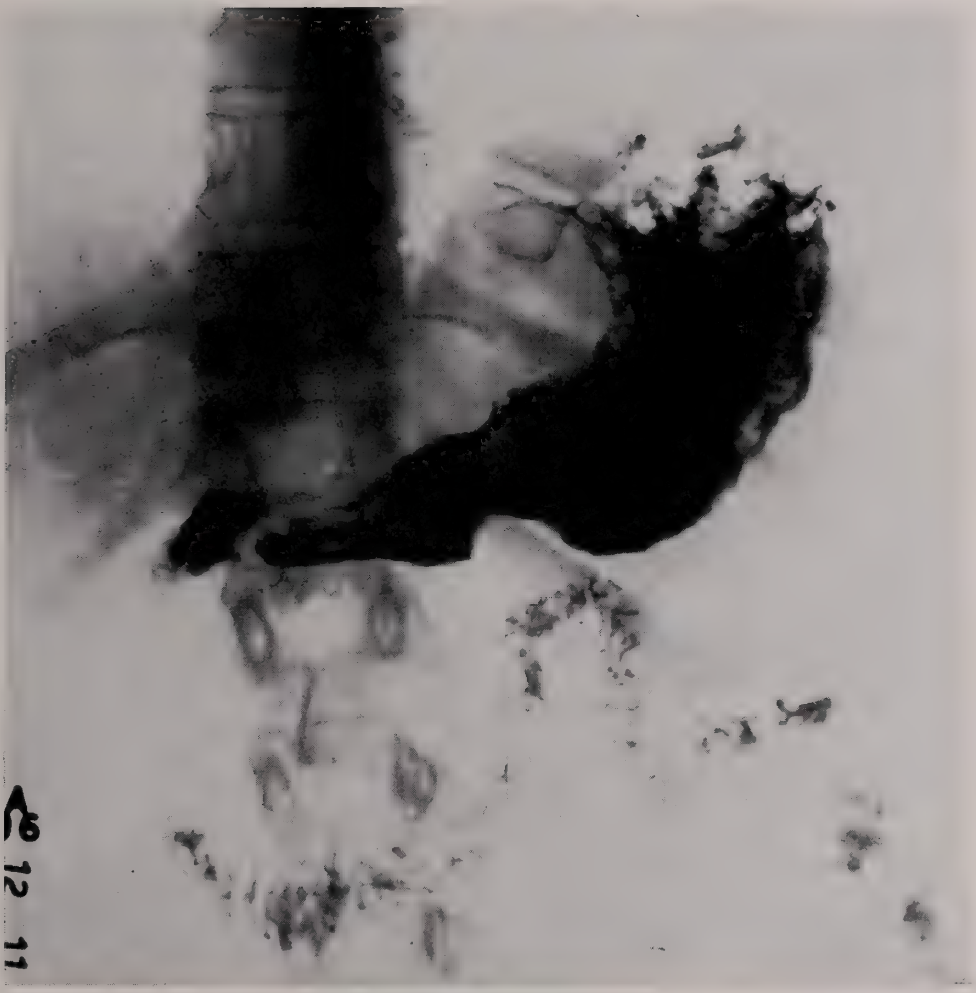

Figure 1

This forty-nine-year-old man was hospitalized with a three-week history of epigastric pain, vomiting, anorexia, weight loss, and pedal edema.

Roentgen examination of the stomach (Figure 1) demonstrated large, ineffaceable mucosal folds of the fundus and body. The gastric wall was thickened. No peristaltic activity was observed. The radiologist's differential diagnosis included lymphoma, carcinoma, chronic gastritis, Menetrier's disease, and recent gastric hypothermia (freezing).

What is your diagnosis? (See next page)

Diagnosis: Menetrier's disease.

Menetrier's disease is characterized by giant hypertrophy of the gastric rugae. The etiology is obscure. It has been seen in all age groups. The incidence is higher among males. Symptoms, if present, are similar to those of peptic ulcer. Many cases are associated with "weeping" of protein through the gastric mucosa leading to hypoproteinemia and peripheral edema.[1-3] This may be demonstrated by the intravenous injection of I^{131}-labelled polyvinylpyrrolidone (PVP). Leakage of its large molecules due to the exudative gastropathy will cause increased radioactivity of the feces.[4] Some patients harbor multiple endocrine adenomas.[5,6]

The roentgen picture consists of various combinations of the following findings: enlargement of mucosal folds, irregularity of the greater curvature, thickening of the gastric wall, and a peculiar reticular pattern produced by barium mixed with mucus.[7] Differentiation from lymphoma and carcinoma may be extremely difficult.

The patient present here had all the features of Menetrier's disease. His serum protein was 4.2 gm./100 ml. (albumine 2.6 gm., globulin 1.6 gm.). On surgical exploration the stomach showed huge mucosal folds, with microscopic evidence of elongation and increase in number of gastric glands. An islet-cell adenoma was found in the pancreas.

S. H. Tsai, M.D.
Department of Radiology
Hennepin County General Hospital

On Coral

Thirteenth century Vincent of Beauvais, in his enthusiasm over the therapeutic virtues of coral, claimed that it checked hemorrhage, reduced corpulence, drew harmful humors from the eye, cured ulcers, and benefited heart, intestines, and spleen. Suspended over the mouth it stopped stomach-ache; suspended from the neck it prevented epileptic fits.

Lynn Thorndike: A History of Magic and Experimental Science.

Fracture–Trauma Conference

Edentulism and Jaw Fractures

The problems of jaw fractures should never be considered from purely anatomical attitudes. The management of any fracture, simple or complicated, requires the restoration of function. Cosmetic restoration, desirable as it is, is not the primary objective in treatment. Many cosmetically acceptable post-treatment cases are unacceptable from the functional point of view. The patient becomes less enamored of his cosmetic status and more concerned about his functional disability.

The functions of the jaws are fundamentally those of mastication and speech. Mastication is accomplished by the dental apparatus which, properly considered, is a complex system limited not merely to teeth and periodontal structures. The jaws, the muscles of mastication, and the complex temporomandibular joint are all integral parts of the dental apparatus. The temporal and zygomatic bones are also intimately associated, and when these bones are involved in jaw fractures, they often interfere with the temporomandibular articulation and with free movement of the mandible.

Whenever the jaws are fractured there is disruption of the proper vertico-occlusal dimension.* The vertico-occlusal dimension becomes increasingly important in the complex injuries in which alveolar process fractures isolate the tooth-bearing portion from the main body of the bone. If the correct vertico-occlusal dimension is not re-established initially, the impaired function is demonstrated by subsequent temporomandibular joint and muscular disabilities. These problems are further compounded by malocclusion and improper arch symmetry.

Full Complement of Teeth

When either or both jaws are fractured and contain a full complement of teeth, it is relatively easy to accomplish an anatomical and functional reduction by immobilization of the jaws. In this instance, the teeth act as splints and can be interdigitated with minimal difficulty.

---

*The vertical dimension of the face when the teeth (or substitute) are in central occlusion.

Continued

Individual Teeth

Any consideration of jaw function concerns the teeth individually and as a unit with multiple complex functions. Each tooth is encased in its own membrane and functions separately and in unison with its neighbors to help establish the jaws in proper functional and rest positions. Correct placement of the condylar head in the glenoid fossa is thus achieved. This concept becomes particularly important when jaws have to be immobilized for several weeks during the period of active osteoid formation. If the teeth, dental arches and jaws are not properly related, occlusal disharmonies result which cannot be corrected except by extensive new surgery. When individual teeth are fractured, lost, or displaced from their alveoli, the reduction becomes difficult and complicated. The management of such cases demands specialized dental knowledge.

Edentulism

When patients suffering from jaw fractures are totally edentulous, the management becomes even more complex. This is particularly evident when the patient does not wear dentures, or if the dentures are lost or beyond repair. These cases usually require open surgery with fabrication of properly designed splints to aid in the immobilization and reduction of the fractured jaws. The construction and placement of such splints requires the special knowledge of the dental discipline. It can be safely stated that in every case requiring splints of a dental nature, the splints must be regarded as substitutes for the missing teeth. Therefore, splints have to conform to the functions expected of natural teeth in establishing and maintaining the proper vertico-occlusal dimension. The purpose of this paper is to demonstrate how such splints are used to aid in the management

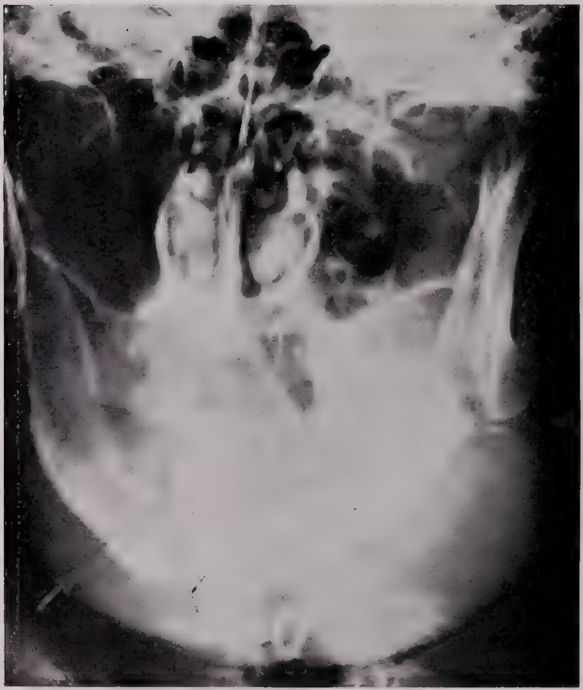

Fig. 1 — Note the obvious deformity of the body of the mandible with the proximal fragment displaced superiorly and laterally.

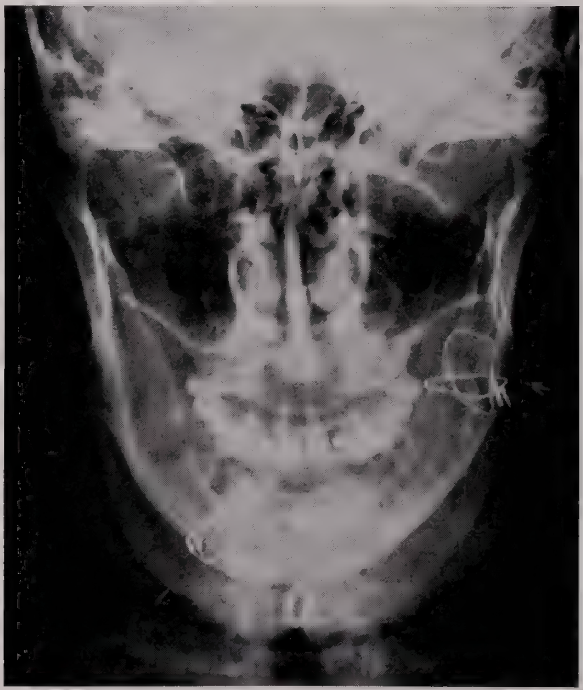

Fig. 2 — A good postoperative result with symmetrical continuity of the mandible adequately demonstrated. Note placement of wire sutures.

of the edentulous jaw fracture.

Three cases of total edentulism will be presented to illustrate the rationale and indications for the use of splints in the case of jaw fractures ranging from relatively simple to very complex.

Case Reports

Case 1

A 60-year-old negro man was struck on the jaw seven days prior to admission to Detroit Receiving Hospital. His physical examination on September 28, 1964, was within normal limits except for an obviously compounded, bilateral fracture of the mandible. His complaints relative to the jaw were pain, paresthesia of the inferior lip bilaterally, and dysfunction of the mandible. The radiographic study of the jaws demonstrated a bilateral fracture of the mandible with gross displacement (Figure 1).

Since the patient was wearing dentures which were functional, there was no need to fabricate new splints. An open reduction was performed on September 30, 1964, via the submandibular approach. The fractures were reduced and maintained in position by transosseous criss-cross wires.

The dentures were inserted on the first postoperative day and occluded in centric relation. This position was maintained by a Barton bandage which tended to limit and restrict the movement of the mandible without completely immobilizing it. The patient was discharged after one week of uneventful postoperative course.

The Barton bandage was removed six weeks after treatment, and follow up X rays taken thirteen weeks after original surgery revealed good anatomic symmetry (Figure 2). The patient functions normally in all masticatory movements.

This case demonstrates the application of the patient's dentures as splints to restore the proper vertico-occlusal dimension. It also demonstrates that complete and firm immobilization of the jaws is not always mandatory for every case of jaw fracture, but that adequate immobilization or limitation of movement produces good results. It is the opinion of the authors that some movement of the fractured mandible stimulates early osteoid formation. The open reduction and firm approximation of the fractured

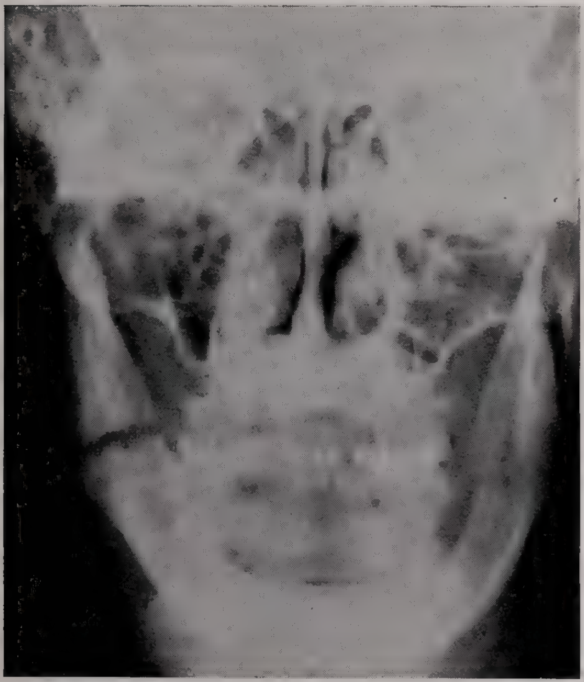

Fig. 3 — Note the laterally displaced proximal subcondylar fracture on the left, and the relatively undisplaced fracture on the right. (The patient is wearing a maxillary denture.)

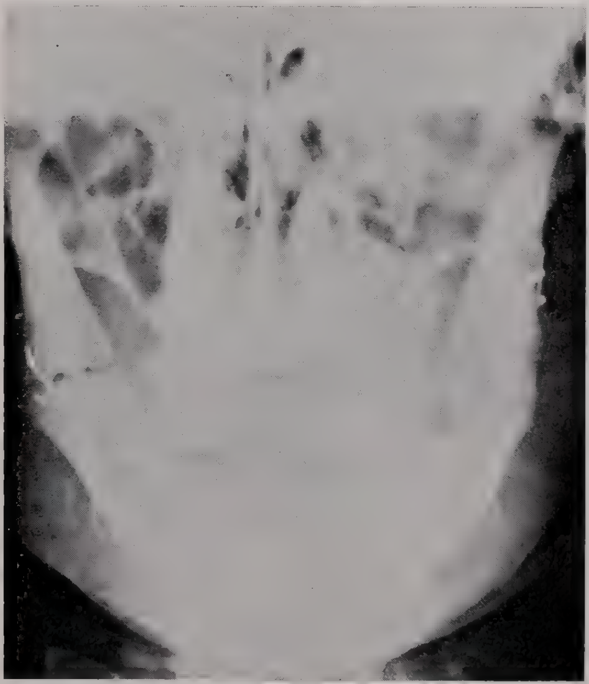

Fig. 4 — Postoperative result demonstrating splint application with four circum-mandibular wires. Note placement of wires in left subcondylar fragment with marked improvement of displacement.

Continued

parts by adequately placed transosseous wires resulted in a very sturdy anatomic mandible requiring minimal postoperative fixation.

Case 2

A 61-year-old negro man was beaten and robbed on June 27, 1964. He was examined at Detroit Receiving Hospital. The radiographs demonstrated fractures of the right angle and the left subcondylar process of the mandible (Figure 3). Laboratory findings were within normal limits and, except for the mandibular fractures, the physical examination was essentially negative.

Since open reduction was decided on as the treatment of choice, prosthetic splints were prepared prior to surgery. On July 3, 1964, a bilateral open reduction was accomplished via the submandibular approach, employing transosseous wires to maintain the fractured parts in anatomic relation. The mandibular splint was held in position by circumferential wires placed at the time of surgery.

One day after surgery the maxillary splint was inserted and the jaws brought into proper centric-relation and vertico-occlusal dimension by occluding the splints, with a Barton type cohesive gauze bandage employed to maintain this relation. The bandage was removed five weeks after surgery, and the patient was permitted to function on a soft diet.

An X ray taken seven weeks after treatment demonstrates excellent anatomic position (Figure 4). The mandibular splint was removed at this time, and it was noted that the mandible functioned normally in all excursions.

This case demonstrates the use of a maxillary denture and the fabrication of a mandibular splint, as the patient did not wear a mandibular denture. The problem in this case was the establishment of proper vertico-occlusal dimension, which was accomplished by fabrication of the splint to occlude with the maxillary denture which was the point of reference for this patient. This case also presents the additional problem of a joint fracture dislocation. The mandibular splint was wired to the jaw in order to accurately relate the mandible to the maxilla. This procedure permitted

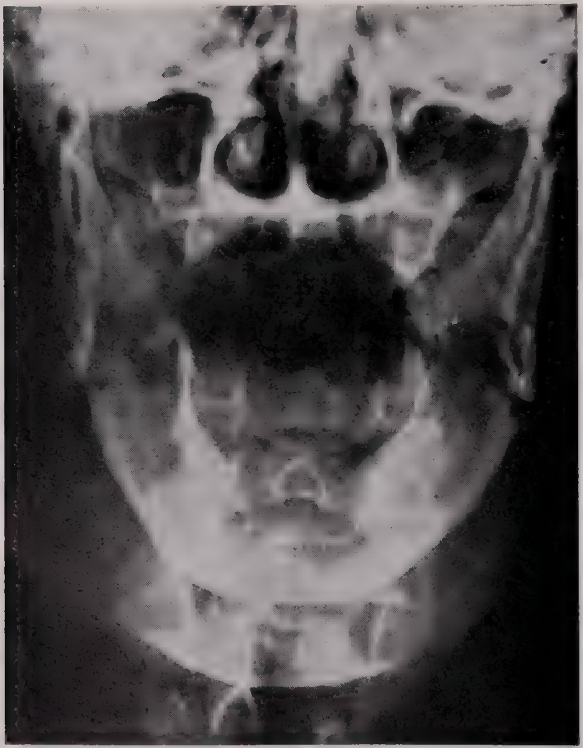

Fig 5 — Grossly displaced, bilateral, comminuted fracture of mandible. Note marked inferior displacement tending to give patient a chinless appearance.

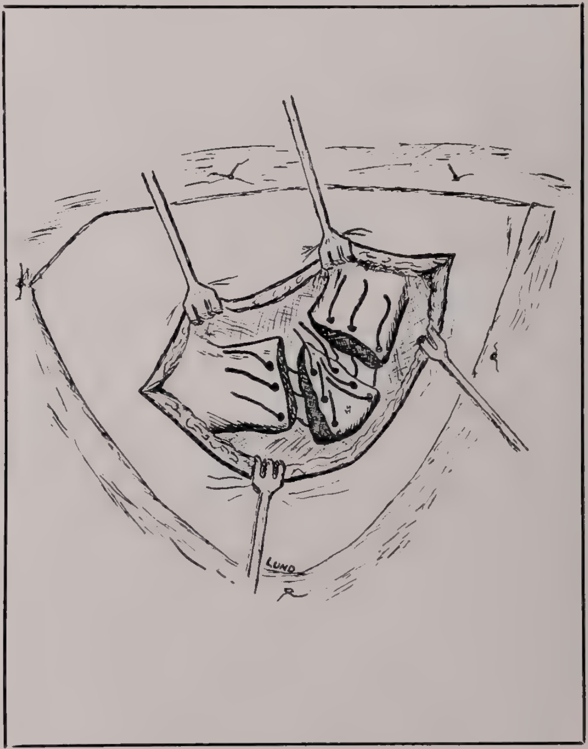

Fig. 6 — Schematic drawing demonstrating the technique of intraosseous wiring employed to replace free bony fragment (autogenous graft).

the jaw and splint to move as a unit without displacement of the mandibular splint. The result obtained indicates that this procedure was efficacious. There was adequate but not complete immobilization of the jaws. The purpose of slight movement was to institute more rapid consolidation of the fractured condyle and to prevent the possibility of ankylosis. It is considered good treatment to mobilize subcondylar fractures in three to five weeks.

Case 3

A 58-year-old white man was first seen in the emergency room at Detroit Receiving Hospital on August 23, 1964. The patient had been beaten six days prior to this visit. For the preceding 72 hours he had been unable to eat or speak because of the resultant edema.

On physical examination there were large hematomas and ecchymosis present bilaterally on the face. The past medical history was noncontributory.

Oral examination revealed a completely edentulous patient, with the fractured anterior segment of the mandible grossly displaced inferiorly.

Radiographic findings revealed multiple bilateral comminuted fractures (Figure 5).

Nine days post admission, the edema had subsided and the patient went to surgery. Bilateral open reductions were performed. Because of the multiple comminutions the fracture reductions were difficult to accomplish. It was necessary to remove a fragment of bone from the operative field and drill six holes through it while it was supported on a board. Corresponding holes were drilled through the proximal and distal fragments of the mandible, and wires were passed through the holes in the free fragment. The fragment was placed in proper anatomic relation, and the free ends of the wires were passed through the corresponding holes in the proximal and distal fragments (Figure 6). The wires were tightened firmly into position, accomplishing an excellent reduction (Figure 7). The left side presented a similar but somewhat less complicated problem.

After the incisions were closed, the previously prepared splints (dentures) were inserted. The maxillary splint was held by circumzygomatic wires. The mandibular splint was maintained by circumferential wires. The jaws were immobilized by intermaxillary fixation in excellent position (Figure 8).

The patient was discharged two weeks post surgery to be followed at weekly

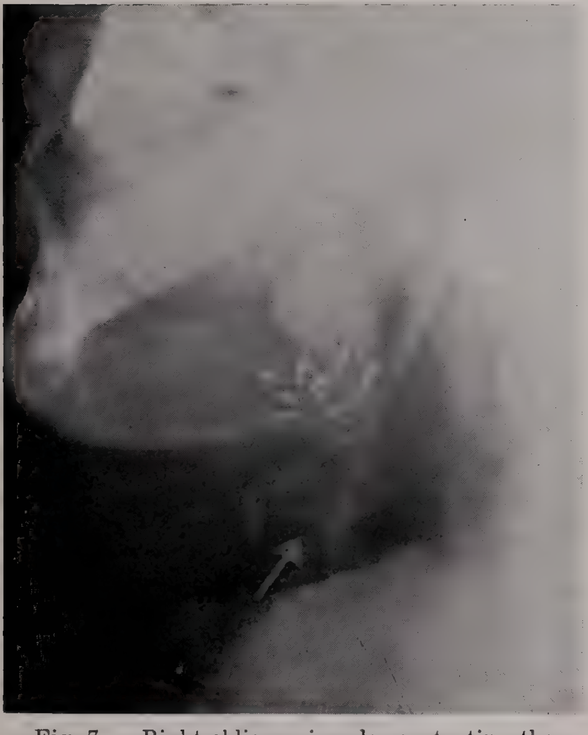

Fig. 7 — Right oblique view demonstrating the replaced bone fragment described in the text.

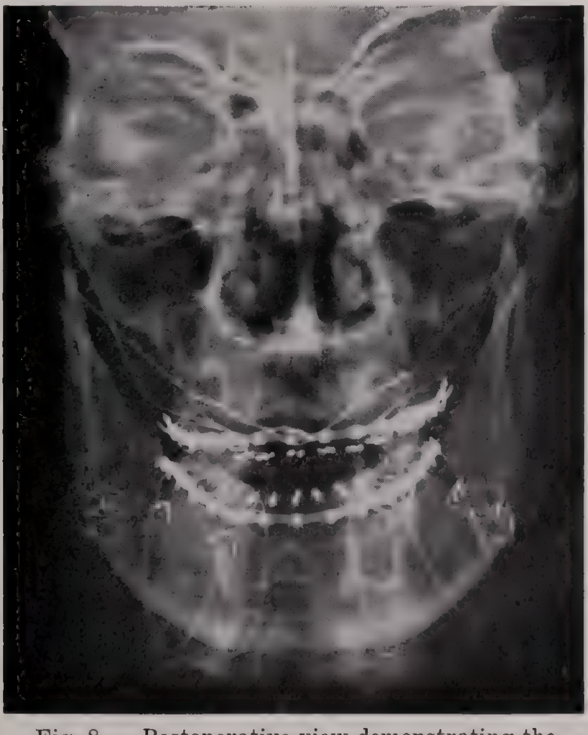

Fig. 8 — Postoperative view demonstrating the fixation of the splints to maxilla and mandible. Note the circum-zygomatic wires and the circum-mandibular wires.

Continued

intervals. The intermaxillary fixation was removed eight weeks after surgery, permitting limited function. After two weeks of limited function, the splints were removed.

Postoperative X rays taken five months later demonstrated excellent anatomical symmetry (Figure 9).

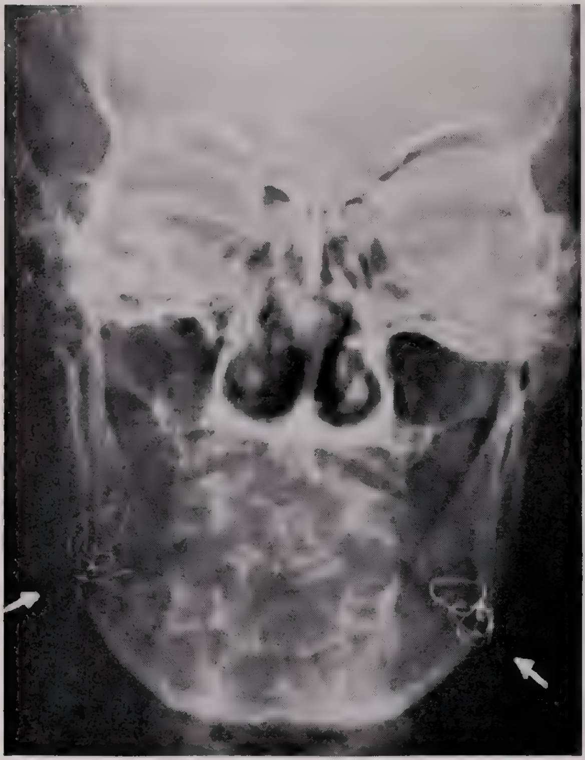

Fig. 9 — Radiographic appearance of the mandible five months after treatment. (Compare with Fig. 5.)

This case demonstrates the absolute necessity of complete and firm immobilization in order to assure a proper healing of the complicated fractures. In this case undue movement would be detrimental and tend to produce failure. Therefore, both maxillary and mandibular splints (dentures) were firmly wired into position to prevent movement. The efficacy of the procedure was demonstrated in the success of this case.

Comments

Patients with jaw fractures should be maintained on a high-calorie, high-protein, liquid diet with vitamin reinforcement. Antibiotics and oral-hygiene care are mandatory. The general systemic care of the patient is supported as necessary.

In Case 1 the prosthetic splints were placed without wiring because of the anatomical reduction obtained and the relative simplicity of the fractures. Adequate immobilization and vertico-occlusal dimension were maintained with craniomandibular fixation. In Case 2, in order to maintain the continuity of the mandible and the proper centric relation, it was necessary to employ circum-mandibular wiring of the mandibular prostheses, thus enabling the mandible and the prostheses to move as one unit. The counteracting forces supplied by the muscular attachments were circumvented by interdigitation with the maxillary denture. This procedure accomplished stabilization of the more fragile condylar fracture. In the third case, certainly complicated by the gross comminutions with the necessity of a free autogenous graft, it was deemed mandatory to wire the maxillary and mandibular dentures into position. This maneuver accomplished a complete and accurate interdigitation of the dentures and immobilization of the jaws, thus insuring a greater probability of success.

Conclusions

In summation it can be stated that to prognosticate favorable results in edentulous jaw fractures the following principles must be maintained:

Maxillary and mandibular prostheses must be constructed to maintain the proper vertical-occlusal dimension.

Anatomical osseous relations must be maintained, when an open reduction is employed, by adequate transosseous wiring.

Proper immobilization of the jaws is mandatory for a sufficient time to allow for the proper osteoid formation.

Good oral hygiene and supportive therapy must be maintained.

It has been our experience that failures in treatment of edentulous fractures can be directly attributable to a failure to observe one or all of the aforementioned principles. All four outlined steps are equally necessary and important for the proper treatment of edentulous fractures. In general, adherence to the principles will produce proper postoperative function and good cosmetic results.

Virtues of Human Parts

From Pliny we learn that various parts and products of the human body are credited with remarkable virtues. A few instances of remedies drawn from the human body are ear-wax or a powdered tooth against stings of scorpions and bites of snakes, a man's hair for the bite of a dog, the first hairs from a boy's head for gout. Simply tying two fingers or toes together is recommended for tumors in the groin, catarrh, and sore eyes. Or the eyes may be touched thrice with water in which the feet have been washed. Scrofula and throat diseases may be cured by the touch of the hand of one who has died an early death, although some authorities do not insist upon the circumstance of early death but direct that the corpse be of the same sex as the patient and that the diseased spot be touched with the back of the left dead hand.*

The cancer with the highest incidence: skin. The cancer with the highest mortality rate: lung. Both, ironically, the most preventable of all cancers.

Lung cancer kills some 47,000 Americans every year. Estimates are that more than 75% of lung cancers are caused by cigarette smoking . . . a preventable habit.

About 80,000 Americans develop skin cancer each year. Since its principal cause is excessive exposure to the sun, preventive measures are clear.

Basal cell and squamous cell carcinoma, commonest forms of skin cancer, are easily cured in their early stages. The high incidence of skin cancer, the suffering, disability and disfigurement which too often accompany it, make it a challenging problem.

In its program of bringing vital facts about cancer to the public, the Society has two new films, both available for showing through any ACS Unit. WHO, ME? dramatizes the hazards of cigarette smoking. SENSE IN THE SUN urges both sun workers and sun worshippers to exercise caution. Like all Society films, their object is to save lives and diminish suffering from cancer by giving forceful expression to many of the facts about cancer with which you, doctor, guide your patients.

Tumor Anomaly Conference

Reflux in a Blind Ending Ureter: Experiment of Nature

The investigation of all cases of pyuria in the male is one of the cardinal principles of urology. The trail may often lead to the more common conditions of prostatism, stricture, or calculus disease, but on occasion unexpected and oftentimes puzzling conditions are discovered.

Case Report

A 56-year-old man entered the hospital with dull recurrent left flank pain of 25 years' duration. He was first seen in 1962 with similar complaints. At that time he

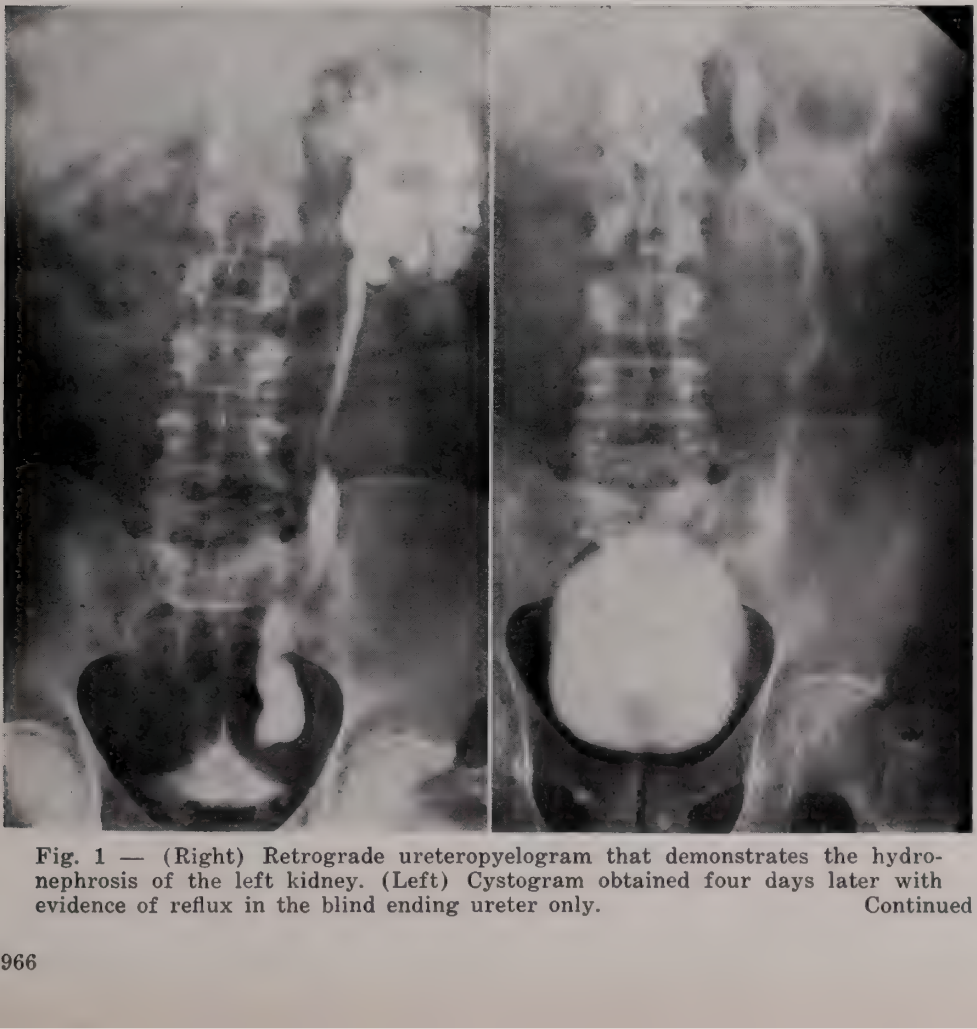

Fig. 1 — (Right) Retrograde ureteropyelogram that demonstrates the hydronephrosis of the left kidney. (Left) Cystogram obtained four days later with evidence of reflux in the blind ending ureter only.

Continued

had marked pyuria with a B. proteus isolated from the urine. An excretory urogram showed duplication of the right ureter and pelvis and nonvisualization of the left kidney. The patient refused further diagnostic procedures at that time, but returned two years later with identical complaints and submitted to further diagnostic studies. An excretory urogram was similar to the one done previously. A cystogram (Figure 1) showed reflux up a left ureter to the pelvis without visualization of calyces. Marked left ureteropyelocaliectasis* was demonstrated on retrograde ureteropyelograms. At the time of cystoscopy no evidence of vesical outlet obstruction was noted. Single right and left ureteral orifices were observed. However, the left was more patulous than the right. A B. proteus, resistant to all antibiotics, was isolated in the urine from the left kidney and from the bladder. Renal function studies were within normal limits. A nephroureterectomy was recommended, but the patient decided to postpone this until a later date.

Three months later the patient returned, and an uneventful left nephroureterectomy was performed. The specimen (Figure 2) showed two dilated thickened ureters, one terminating in an area of fibrous thickening at the upper pole of the kidney, the other in the renal pelvis. The major portion of the parenchyma was thinned, varying from 0.3 to 1.0 cm. Histologic examination of the upper pole showed an area of fibromuscular tissue containing a few scattered tubules, while in the rest of the kidney there was evidence of chronic pyelonephritis. The final diagnosis was renal agenesis of the upper pole of the kidney, double ureter, and hydronephrosis with chronic pyelonephritis.

The patient was discharged with a two-week supply of nitrofurantoin, and on return one month after the nephrectomy he had only occasional white blood cells per high power field in his urine.

When the left kidney was examined and compared to the roentgen studies, it was evident that the reflux demonstrated was present in the blind ending ureter only. This occurred at low pressures as well as high pressure since opacification of the blind ureter (in retrospect) was noted on at least one of the excretory urograms when the bladder was only partly filled.

---

*See Test Your Word Score Page 97.

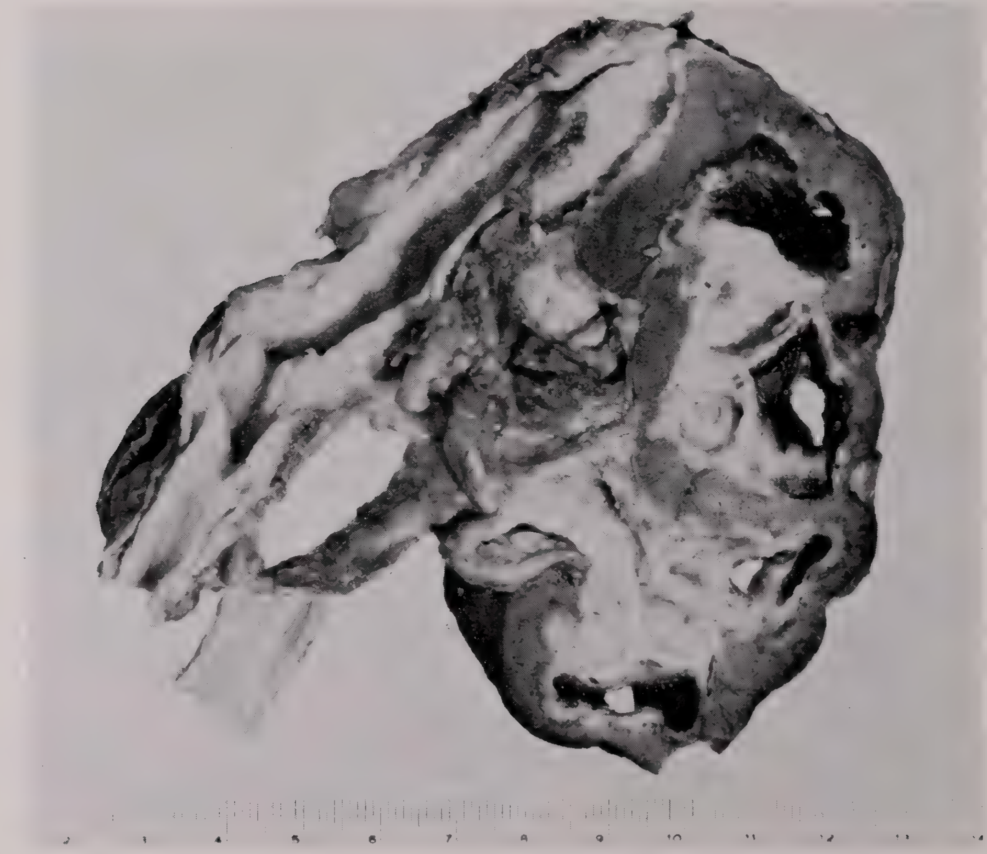

Fig. 2 — Section of the gross surgical specimen. The upper ureter ends in an area of fibrous thickening, while the lower ureter communicates with the renal pelvis and calyces.

Discussion

Ureteral duplication has an incidence of about one in 160 persons with complete duplication present in one in five hundred, and bilateral complete duplication present in only one in three thousand people.[1] Blind ending ureters are even less frequent.

It is axiomatic that the anomalous organ is more prone to disease than the normal.[1] However, it is of interest to speculate why the case presented developed reflux in only one of four ureters.

The ureterovesical sphincteric action has been ascribed to its submucosal length of the ureter (flap valve theory of Sampson[2]), its muscular coat[3] and its intramural length, and the flexibility and fixation of its lower border.[4] The controversy over the pathogenesis of reflux still rages, with advocates of infection, congenital abnormality of the ureterovesical junction, vesical outlet and urethral obstruction, and neuromuscular dysfunction providing additional data for their individual viewpoints.

If one or more of the above reasons for reflux are to be accepted as valid in this case, it must explain why three of four ureters did not reflux and why duplicated ureters with a single orifice should demonstrate reflux in only one of these ureters. Infection alone cannot be blamed for the reflux since it was present for many years; yet reflux was not demonstrated even in the ureter connected with the dilated, infected kidney and pelvis. No vesical outlet obstruction could be demonstrated, and even if it were present, it could not explain reflux in only one of four ureters.

It is doubtful whether the length of the submucosal segment of ureter plays any role in this patient's reflux, since both ureters had the same orifice opening into the bladder.

The only remaining reasonable possibilities are that there was a neurological, muscular or combined neuromuscular defect in the vesical segment of the blind ending left ureter, permitting reflux of urine to occur. Previous reports of similar cases of duplicated ureters by Stephans[3] have led him to emphasize the importance of the intrinsic sphincteric ureteral musculature in the ureterovesical "valve" mechanism.

Unfortunately the difficulties involved in demonstrating neurones in the ureter make this avenue of explanation of reflux hard to prove or disprove. However, the possibility of a neuronal defect does exist and must be considered in this case.

Summary

An interesting case of persistent pyuria with reflux in a blind ending ureter is presented. The various possibilities as to the pathogenesis of the reflux are discussed, and the conclusions reached are that a neuronal, muscular, or combined neuromuscular defect is the most reasonable explanation for the vesicoureteral reflux demonstrated.

Papyrus Ebers[*]

On Bites

The ambit of pathologies catalogued in the Ebers Papyrus covers at least 82 supposedly common ailments in ancient Egypt, most of them all too deplorably familiar to us Twentieth Century mortals. To read a list of them is to so telescope space and time as to induce a close affinity of commiseration between us and those ancient Egyptian brethren of ours. After all, what else can so effectively make the whole world kin as headache, indigestion, constipation and coryza!

Bites further confirm our sense of consanguinity. Whereas our bites are more commonly dog or mosquito-inflicted, with the Egyptians the agents appear to have been crocodiles and — people!

"Three thousand years ago, we are forced to assume, bites from crocodiles were about as common as black eyes in these days; and to carry the simile still further, both were treated in the same way:

What to do Against the Bite of a Crocodile:

If thou meetest a Crocodile's Bite, and thou findest his flesh equally fallen away on both sides, so thou coverest it with Raw Meat the first day.

"A wound that merely demands a piece of raw meat to be clapped on it the first day could hardly be placed elsewhere than under Minor Surgery. Even a bite that one might suffer at the hands, or rather the teeth, of a lady or gentleman friend required more intensive treatment than that demanded by the bite of a crocodile."

Remedy Against the Bite or Sting of People:

Make thou for him a poultice of Raw Flesh on the first day. Afterwards treat him with Oil and Honey in order to do him good. Then put thou Oil in Wax in order to make him completely well at once."*

For Abdominal Troubles

Marcellus Empiricus (5th century A.D.) recommends pressing the abdomen with the left thumb and saying, "Adam, bedam, alam, betur, alem, botum." This is to be repeated nine times, then one touches the earth with the same thumb and spits, then says the charm nine more times, and again for a third series of nine, touching the ground and spitting nine times also.*

We cry loudly for a man of vision and when we get one we call him a visionary.

Athletic Injuries

Management of Head and Neck Trauma Secondary to Athletic Injury*

As participation in various athletic events increases at the grade-school, high-school and college levels, it is logical to assume that the number of related injuries likewise will increase. It is imperative that the team or local physician responsible for the care of these athletes has a thorough knowledge of the initial evaluation and, when necessary, the continued observation of a patient who has sustained an injury to the head or neck. Likewise, he will be responsible for making the decision as to when the injured person may safely return to athletic participation. The purpose of this summary is to lay down some guideposts which may be helpful to those individuals who, serving as team physicians, assume these responsibilities.

Many articles have been published reviewing the type, frequency and severity of athletic injuries.[1-4] Injuries to the head and neck fortunately comprise only a very small percentage of the entire number of injuries. It is signficant, however, that of the fatal injuries incurred, 50% are related to head and neck trauma. With careful initial care, observation, and recognition of signs of deterioration, many of these fatalities can be avoided if prompt definitive care is instituted.

Prior to engaging in competitive sports, the athlete should have a thorough medical examination. If a history of convulsive seizures is obtained, even if adequately controlled with anticonvulsant medication, he should not be allowed to engage in contact sports. Most seizures are probably related to previous cerebral damage either from trauma or disease processes. It seems only logical that such an individual should be kept away from situations wherein he would be subjected to further direct trauma.

Thorndike[4] has stated that if an athlete has a history of three or more concussions, he should not be permitted to engage in further contact sports. I would tend to agree with Murphey and Simmons' view: viz., that "each case is a highly individualized matter, and the exact severity of the brain injury has to be decided upon in each case."[2] If, after thorough investigation, no evidence of brain damage is found, it is probable that such an individual can engage in contact sports without any greater risk than those who have not had such injury.

Among those conditions which absolutely preclude participation in contact sports are: previous fracture dislocations of the spine, laminectomy for tumor or intervertebral disc herniation, arteriovenous malformations, intracerebral aneurysm, and all post-craniotomy states.

For purposes of classification, trauma to the head can be grouped into three categories.

The first and largest group comprise those athletes who, following direct

---

*See Minnesota Med 48:1665 for fourth in this series. Sponsored by Minnesota Committee on Trauma of the American College of Surgeons.

Continued

or indirect head trauma, are momentarily "stunned," disoriented or unconscious. Such individuals usually quickly recover complete neurologic function, both physically and mentally. The great majority of such injuries are uncomplicated and a total recovery ensues. However, it must be remembered that extradural hematoma can occur after very minor trauma. Therefore I feel that *all* such injuries should be hospitalized and observed by trained personnel for at least twenty-four hours. If no hospital facility is available or the person refuses such care, an intelligent observer should watch him carefully for the next 24 hours. During this time the patient should be awakened every hour and note should be made of his orientation, the ease of arousal, motion in extremities, pupillary equality, and normalcy of pulse rate. If any deviation is noted he should promptly be re-assessed by the responsible physician. If the course following injury is uncomplicated, despite pressure from the athlete, coach, or family, this *patient should not engage in contact sports for at least one week.*[2] Slow, insidiously developing extra or subdural hematoma can occur days or even weeks following such injury.

The second group includes those individuals who have had some degree of cerebral contusion. These athletes have more than just momentary unconsciousness, and mental clearing is slow. It is not uncommon to find transient neurologic deficit, dizziness, persistent headache, nausea and/or vomiting. All such patients must be hospitalized and the previously mentioned careful, trained observation instituted. Skull X rays should be made. Any deviation from normal requires prompt emergency neurosurgical consultation. If the course is uncomplicated, *such athletes should refrain from participation in all sports for a minimum of two weeks.*[2] Thereafter, a careful re-evaluation should be made by the physician prior to permitting resumption of athletic activity.

The third group, the most severely injured, is made up of those athletes who are slow to regain consciousness, those with progressive neurologic deficit and those with depressed and/or compound skull fracture. There is no doubt that all these patients should be immediately hospitalized and, when necessary, transfer to a neurosurgical facility made without hesitation. If the patient is having acute respiratory trouble or is in shock, secondary to blood loss, correction of these situations should obviously be made prior to transfer. At the time of transfer a trained nurse or medical aide familiar with the use of suction apparatus and administration of O_2 should accompany the patient. Such patients should at all times have a free airway, as the use of oral airways and suctioning of excessive secretion can be of paramount importance. These patients should be transported on their side in order to minimize aspiration of vomitus and secretions. Narcotics are contraindicated in the early management of any head injury.

The prognosis for recovery in this third category of head injury is not as good as in the previous groups. However, with prompt initial care and intervention when necessary, the outlook has definitely improved. No matter how complete the recovery, *such athletes should be permanently barred from participation in all contact sports.*[2]

Cervical spine injuries of serious consequence may occur with participation in contact sports. The frequency of such occurrence is much less as compared to head injury. However, with the wide adoption of the protruding face protector on football helmets we may see increasing numbers of cervical spine injuries. The mechanisms involved in producing such injury have been extensively studied by Schneider et al.[3]

The clinical picture in cervical spine injury has wide variation, consisting of minimal pain and stiffness in the neck at one extreme to the tragic state of quadriplegia at the other. Again, as with head injuries, three broad groupings of cervical spine injuries may be discussed.

The first group comprises those individuals who have complaints of pain and stiffness in their neck without neurologic deficit. This is far and away the most common group that will be encountered. All such patients should have thorough X-ray study of their cervical spines in the anteroposterior and lateral views plus open-mouth views for the odontoid. It is imperative that the entire body of *all* cervical vertebrae be visualized. Occasionally it may be necessary to pull down on the arms at the time of the X ray to see the C7 body completely. Films that do not fulfill these stipulations are inadequate. It is surprising to see an occasional patient who, some days to even weeks following apparent minor injury to the neck, proves to have a fracture dislocation of his cervical spine without neurologic deficit.

If no abnormality is noted on the X rays, symptomatic, nonsurgical treatment is in order. Resumption of participation in athletics may then be resumed when a full range of motion of the neck is possible without pain or muscle spasm.

The second group comprises those individuals who have neurologic deficit. These people may have obvious weakness, or complain of numbness, or tingling in their extremities, particularly the arms and hands. The occurrence of such signs and symptoms should never be disregarded even though improvement appears to be taking place. One should treat *all* such injuries as potentially serious cervical spine fracture dislocations. These athletes should be transported on a stretcher or board with their heads held immobile. Mild head halter traction of 5-10 lbs. weight, when available, is excellent. Sand bags applied to each side of the head will help prevent lateral motion. Such transportation can be made in the supine position. However, if any complaints of nausea are present, transportation in the prone position (again employing measures for immobilization) is indicated. Someone should always be in attendance when these individuals are moved.

It is apparent that these athletes, even if roentgenographic studies are normal, have sustained significant trauma to the cervical spine. Even though complete recovery obtains, these athletes should *not* participate in contact sports and should be prohibited from diving.

The third group are those unfortunate people in whom paraplegia or quadriplegia is in evidence from the outset. The need for transportation to a neurosurgical facility is obvious and the previously mentioned mode of transport should be utilized. The prognosis for recovery unfortunately is extremely poor. A small percentage of these people will prove to have the syndrome of acute central cervical cord injury.[3] In that group recovery of lower extremity function occurs first, with a gradual ascending return of function that may be complete or only partial.

Summary

1. A brief outline for initial care and management of athletic injury to the head and neck has been made.

Continued

2. Certain general rules governing further participation in athletics have been set forth. It is emphasized that these should serve only as guideposts and that a good deal of individual variation exists.

Anglo-Saxon Leechcraft

For broken head, take betony: bruise it and lay it on the head above; then it unites the wound and healeth. Again, for the same: take garden cress, that which waxeth of itself, and is not sown; put it in the nose, that the smell and the juice may get to the head.

If the shanks be broken, take bonewort, pound it, pour the white of an egg out, mingle these together for the man whose shanks are broken. For a broken limb, lay this salve on the broken limb, and overlay with elm-rind, apply a splint; again, always renew these till the limb be healed. Clean some elm-rind and boil it thoroughly, then remove the rind, take ground linseed and brew it up with the drink of elm. That shall be a good salve for a broken limb.

If a man be wounded on the top of his head and the bone be broken, take sigelwherf (probably margold) and white clover plants and woodruff; put into good butter and strain through a cloth.

If the shoulder get up out of place, take the salve, apply a little warm with a feather; it will soon be well with the man.

For cancer take goat's gall and honey, mingle together of both equal parts, apply to the wound. Burn a fresh hound's head to ashes, apply to the wound. If it will not yield to that, take a man's dung, dry it thoroughly, rub to dust, apply it. If with this thou art not able to cure him, thou mayst never do it by any means.

For hare-lip, pound mastic very small, add the white of egg, and mingle as thou dost vermilion, cut with a knife, sew fast with silk, then smear without and in with the salve, ere the silk rot. If it draw together, arrange it with the hand; anoint again soon.

If a man's bowel be out, pound galluc (comfrey), wring through a cloth into milk warm from the cow, wet thy hands therein, and put back the bowel into the man, sew up with silk, then boil him galluc for nine mornings, except need be for a longer time. Feed him with fresh hens' flesh.

If thou wilt carve off or cut off a limb from a body, then look thou of what sort the place be, and the strength of the place, since some of the places readily rot if one carelessly tends them; some feel the leechdoms earlier, some later. If thou must carve off or cut off an unhealthy limb from a healthy body, then carve thou not it on the edge of the healthy body; but much more cut or carve on the whole and living body; so thou shalt better and readier cure it.*

Neurological Conference

Difficulty Hearing and Seeing in an Elderly Patient*

Dr. Donald Soll:*

This 73-year-old-woman entered with the complaint of blurring vision and hearing loss of many years' duration. She has had a history of very small pupils for at least 30 years; nevertheless, her sight had been fairly good until she began to note increasing haziness of vision in her right eye about five years ago. As a child, she had considerable ear trouble resulting in the loss of her left ear drum and decreased hearing in both ears. This hearing loss has forced her to use a hearing aid for approximately the past 20 years. In recent years her hearing aid has been gradually less satisfactory.

History

The patient's past medical history is significant in that she has had a history of heart trouble and high blood pressure since 1963, which has been treated conservatively with diuretics, digitalization and nitroglycerin. Also she has had a mild diabetic condition controlled fairly well by diet. Interestingly, she was involved in an auto accident about 30 years ago and sustained a skull fracture on the right side of her head. Her mother died of stomach cancer and her father had arteriosclerosis. She has had no known venereal disease.

Physical Findings

Physical examination revealed a frail elderly woman weighing 86 pounds. She was quite alert but had difficulty hearing even with her hearing aid. Her blood pressure was 200/80 mm.Hg. and her pulse slow and regular at 52/minute. There was an absence of left tympanum; the right tympanic membrane was markedly sclerosed but intact. The remainder of the general examination was unremarkable except for a distinct bruit over the abdominal aorta.

Continued

Neurologic Evaluation

On neurological examination the deep tendon reflexes were very brisk yet equal bilaterally, and plantar stimulation produced plantar flexion. Muscle strength, sensation, and coordination were likewise intact. The pupils were pinpoint and completely unresponsive to light or accommodation. A combination of mydriatics also failed to significantly dilate the pupils. A partial superior temporal quadrantanopsia was noted in the left eye during examination of the visual fields. The Rinne's test revealed a greater bone conduction than air bilaterally. The Weber test showed no lateralization.

Ophthalmological Findings

Ophthalmological consultation was obtained and the patient's visual acuity was found to be 20/70 without glasses and 20/60 with glasses in the left eye. The acuity in the right eye was less than 20/400 with or without glasses. Bilateral cataracts were noted, but these were not felt to account completely for the patient's decreased visual acuity. Early glaucomatous cupping was considered a distinct possibility.

Laboratory Determinations

Routine hemoglobin, blood count, and urinalysis were within normal limits. A two-hour postprandial blood sugar was 120 mg.%. The stool guaiac was negative. Several blood chemistries including serum proteins, cholesterol, and electrolytes were normal. A flat film of the abdomen showed calcifications, probably localized within the splenic artery and aorta.

An area of irregular calcification was found situated above the sella turcica on the skull x-rays, supporting the possibility of a brain tumor. (See Figures 1 and 2.) The electroencephalogram revealed bilateral central spikes and an intermittent slow wave focus in the left anterior temporal area compatible with a space-occupying lesion of focal atrophy, more

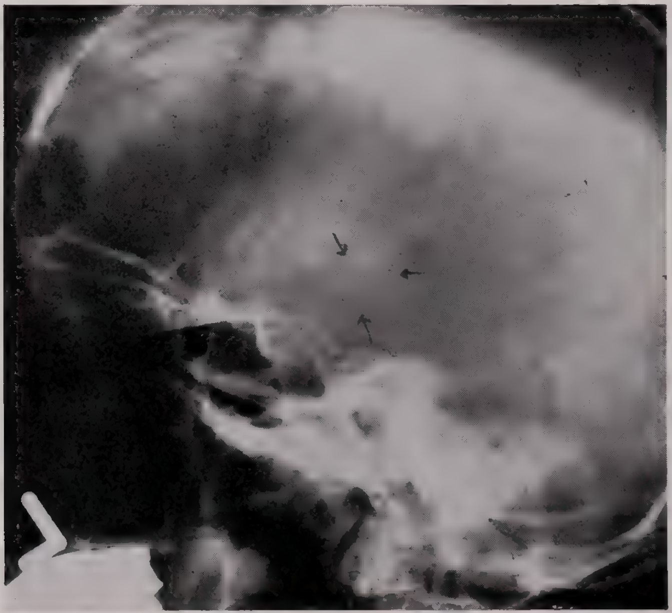

Fig. 1 — Lateral view of skull reveals a curvilinear calcification located slightly superior and posterior from the dorsum sellae. In both Figures 1 and 2, arrows point out abnormal intracranial calcification within the mass.

likely the latter. A brain scan was subsequently performed which was highly suggestive for the presence of an area of increased radioactivity in the suprasellar area.

Bone and nerve conduction were both reduced to such an extent that it was felt tympanoplasty would not benefit the hearing in the left ear. Neurosurgical evaluation considered a craniopharyngioma to be the most likely explanation for the x-ray findings on the skull films.

Dr. Roy Good:*

I have seen this patient for the past six or seven years, mostly for treatment of her cardiovascular problems. My primary reason for this referral was for evaluation of her visual problems, as she had complained to me that her vision had diminished sufficiently to interfere with her capability of reading and getting around the house. On cursory examination I felt that she was most likely developing a cataract.

Dr. Robert Soll:**

On neurological examination there were no objective findings that might further support the possibility of a brain tumor other than the visual field defect. The presence of suprasellar calcification on the skull x-rays did indicate, however, that this abnormality was a long-standing lesion, apparently causing little difficulty in previous years.

Our initial impression was that this represented an intravascular calcification within the intracranial portion of the carotid artery. The other possibility was a benign, very slowly growing tumor, which became much

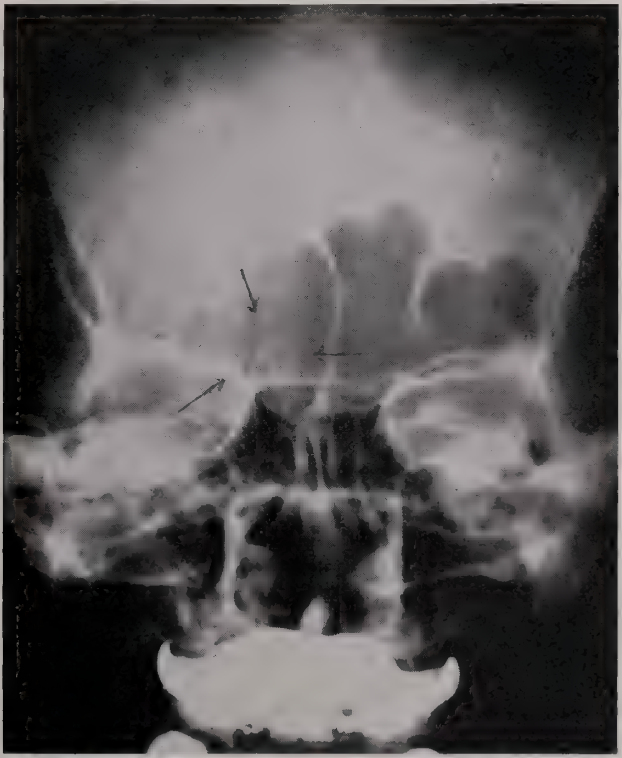

Fig. 2 — Anterior posterior projection of the skull shows more of an irregular calcification located to the right of the midline (outline by arrows).

---

*Referring physician.

**Neurologist, University of Minnesota Hospitals.

Continued

more probable when the brain scan was noted to show a tumor stain in the same area.

Her pinpoint pupils quite likely have no relationship to this tumor; their cause must be attributed to some event happening at least prior to 30 years ago. In some animals, including man, the sympathetic supply to the iris courses through the middle ear by accompanying the tympanic branch of the ninth cranial nerve. Severe middle-ear disease could cause the destruction of this sympathetic supply and thus produce miotic pupils.

Miss Anne Seltz:*

The Audiology Clinic revealed that she had a severe degree of bilateral sensori-neural loss in addition to a bilateral conductive (middle ear) loss. The technique of masking the ear not being tested cannot be applied when the degree of hearing loss is severe. The patient understands speech better when her left ear is amplified. This could support a greater sensorineural loss on the right side.

The patient is presently wearing an on-the-body type of hearing aid. Our routine hearing evaluation includes judging the patient's ability to hear and understand speech with and without a hearing aid. It would be physically more comfortable for her to wear the ear-level aids; however, due to present-day limitations of hearing aids, she would probably be unable to receive sufficient amplification from the small instruments. Her inability to understand speech is not a result of a poor aid but of her degree of sensorineural hearing loss. What she hears is not only too soft but also distorted and unclear. The aid can only amplify sound.

Dr. Robert Soll:

The fact that the right ear drum is intact might imply that more damage had occurred to that ear due to the lack of adequate drainage. Dr. Brantner's* report of the patient's psychological tests reveals that her verbal IQ is 130. Her memory is excellent and there is no evidence for mental deterioration. A Graham Kendall test, which is a memory test for designs, and a Stanford Binet vocabulary test revealed that the patient's definitions of some words were the best given by anyone; for example, the word frustration was defined as "someone preventing you from doing something that you want very much to do."

Dr. John Brantner** knew that we were considering the possibility of her having a brain tumor. His conclusion from the psychological testing was that if she did have a tumor, it must be some type of benign, encapsulated, slow-growing tumor located in the frontal region of the brain.

Miss Helen Kretchmer:†

I saw the patient together with her two daughters. She is a little woman, nicely dressed, alert, and participating. She is one of twelve children. She was educated through the eighth grade and was married at 19. Initially she and her husband homesteaded one year in North Dakota; she was then advised by her physician to return to Minnesota because of her health. She has lived in her present home for over 35 years. Her husband was an oil dealer. Financially, they were comfortable and had a large home which she gave up at the time of her husband's death six years ago.

---

*Department of audiology, University of Minnesota Medical School.

**Assistant professor of clinical psychology, University of Minnesota Medical Center.

†Supervisor and assistant professor social service, University of Minnesota Medical School.

The patient is an accomplished seamstress and has done upholstery work, slipcover and drapery making in her home. She was still doing some work as recently as last year. She now lives with one of the daughters. Her son has helped assist her financially. Her income derives from a $50 a month contract for deed from a piece of property left by a deceased brother plus the social security from her husband's employment, totaling approximately $100/month. Medical Aid for the Aged pays her medical expenses at home and she has county authorization for her care here.

The patient's apartment is in the downtown area convenient for shopping. Stairs are a problem for her because of her visual loss.

The patient has had as many interests as her physical capacity can encompass. She visits her family and travelled alone on the bus until recently. She is head of the devotions committee in church and belonged to a study club and a social club of which her husband was a charter member. She reads prodigiously and works crossword puzzles, to which she attributes her wide vocabulary. The books that she enjoys reading include Westerns, Perry Masons, and love stories. Living in a college town with its many social-cultural advantages, she probably has a broader life than many elderly people who live here in the city.

Dr. Charles Hewell:*

The importance of this patient's skull films is that they show a definitely abnormal calcification within the brain, apparent on the lateral view of the skull above the sella turcica. On an anteroposterior projection it is located to the right of midline. The lateral view gives this density a curvilinear appearance which would suggest the possibility of a vascular structure such as a tortuous vessel or a sacculated aneurysm. Another possibility is a slow-growing brain tumor. The reason that we have to say "slow" is because of the presence of calcification, and the fact that there is no evidence of chronic increased pressure. She has not decalcified her dorsum sellae, nor are the clinoids eroded.

There is an appearance on some views of an irregular rather than a curvilinear calcification, which could favor a tumor. An astrocytoma, oligodendroglioma, or meningioma would likewise have to be considered. Also, a craniopharyngioma would be another possibility; but the fact that it is not midline and that she is rather old is against this diagnosis. Furthermore, there is no tendency for craniopharyngiomas to calcify in the older patient as they do in children. The roof of the sphenoid sinus, the planum sphenali, appears to be pushed down on the right, which could mean that this structure is attached to a slow-growing tumor such as a meningioma.

A brain scan was done using a fast-acting isotope called Technetium which makes it possible to perform the test within an hour after injection. This patient's scan showed evidence of increased activity in the same region as the calcification, but I feel this is questionable. If the test is positive, it would favor some type of vascular tumor such as a meningioma or astrocytoma. The diagnosis probably could be made by angiogram.

---

*Instructor, radiology, University of Minnesota Medical School.

Continued

Dr. Robert Soll:

Dr. Chou pointed out a technical difficulty from the neurosurgical point of view, due to the patient's frontal sinuses which are so large that the approach would have to be very high on the forehead, thus necessitating considerable canipulation of the brain in order to expose the tumor. There is also a possibility of infection from the sinuses.

Dr. Shelley Chou:*

Unless the patient is having a lot of trouble symptomatically, I would not be interested in doing an angiogram. We have evidence of calcification in the suprasellar area; we also know that she has some visual field change which is consistent with a suprasellar mass. It is conceivable that this could be an aneurysm, but from the visual field standpoint I think the probability is that this lesion is a tumor rather than an aneurysm. A craniopharyngioma may extend into the temporal lobe. I would not favor oligodendroglioma because it should show more of a stippled calcification than is present here, and this type of tumor is usually found in the frontal lobe. Regardless of whether she has an aneurysm, meningioma or a craniopharyngioma, I would recommend waiting. An angiogram would be nice to have, but cerebral angiography in this age group is not without risk.

Her symptoms are mostly visual and I would suspect that part of the problem is not related to the field defect but rather to the pupillary changes and cataracts. Therefore I would favor trying to correct these first. It is very unlikely that she will suffer much harm from the intracranial lesion. If it were to grow more, there is a slight possibility that she might develop signs of increased intracranial pressure because of obstruction of the ventricles.

Dr. Hewell:

Why doesn't she have evidence of long tract signs? Have you seen many craniopharyngiomas in this age group?

Dr. Chou:

First of all the lesion is sufficiently forward to prevent impingement on the pyramidal tracts; also, these tumors grow very slowly, thus permitting the brain and brain stem to accommodate to them.

Craniopharyngiomas are seen either in the very young patient, eight or 10 years of age, or in the sixty or seventy age group, skipping over the young adult and middle-aged patients.

Dr. Donald Soll:

The initial opinion of the ophthalmological consultant was that the patient had glaucoma, manifested by an appearance of cupping of the disc. After all tests for increased intraocular pressure proved negative it was felt that some optic atrophy most likely accounted for this appearance of the nerve head as well as for her decreased vision. Her visual acuity is only finger-counting ability in the right eye.

The possibility of cataract extraction has been considered for improving her vision. The ophthalmologists would like to re-evaluate the patient after using neosynephrine drops for two or three days in an attempt to get her pupils more widely dilated.

---

*Associate professor, neurosurgery, University of Minnesota Medical School.

In conclusion, the following points can be made:

1. The patient should be followed but no further diagnostic tests made in regard to the intracranial lesion unless signs of increased intracranial pressure or other complications occur.
2. Another ophthamological evaluation should be obtained in order to determine if cataract removal will significantly improve her vision.
3. Hearing tests should be made to evaluate the possibility of her using binaural hearing aids to advantage.
4. The complete health status of the patient should be reviewed with her daughters, particularly emphasizing the above points.

Dr. Good:

I completely agree with this evaluation. If I had a choice, I would rather have her fitted with the appropriate aid to obtain good hearing than have the cataracts removed. I feel that it is much more important for a person of her age and intelligence to have adequate hearing for the exchange of information. In my experience, people with hearing losses are much worse off psychologically than those who are blind.

Robert W. Soll, M.D. Chairman
Adult Community Services
University of Minnesota

Participating in the conference were Miss Kretchmer, Supervisor and Assistant Professor Social Service; Student Doctor Donald Soll; Miss Anne Seltz, Department of Audiology; Dr. Shelley Chou, Associate Professor, Neurosurgery; Dr. Charles Hewell, Instructor, Radiology; Dr. Roy Good, Referring Physician and Dr. Robert W. Soll, Neurologist.

Experitissimum

Experitissimum was Gilbert of England's magical formula for treating epilepsy in the thirteenth century: At the first access of the disease, when the patient falls to the ground, all his clothes except his shirt should be removed and placed at his feet. The nails of all his fingers and toes should next be clipped and wrapped in a cloth. A long white thorn is then to be split and the patient dragged feet first through the cleft as far as his middle. The thorn should then be cut into bits and placed with the nail parings. Next the patient's hair should be cut in three places. These clippings of hair and the knife used in the operation are then to be added to the other paraphernalia wrapped in the cloth, and the whole is to be buried underground, and the following words uttered. In the patient's right ear, "Christ conquers"; in his left ear, "Christ reigns"; and to his face, "Christ commands."

Life's taxi keeps on marking up the nickels, whether you are driving anywhere or just sitting still. — Cominco Magazine

Akhnaton

Was Akhnaton (Amenhotep IV), who ruled Egypt from 1375 to 1358, a victim of Froelich's syndrome, paleopathologists ask. Precise diagnosis from his remains is impossible, since the bones of the King were long ago partially crushed by the pressure of faulting rocks on his coffin; but study of the intact portions leads scientific observers to the tentative diagnosis of Froelich's syndrome: dystrophia and adiposo-genitalis. Careful examination shows delayed consolidation of the bones, slight hydrocephaly and acromegaly — with a somewhat feminine contour of figure.

Akhnaton was married to his half-sister, Nefertiti, who is said to have so markedly resembled him that as dressed-alike children they were hardly distinguishable. History records that he sired several daughters by Nefertiti; whereupon science asks: Could he have? and then replies: Yes — on the assumption that during his teens, the period when young Egyptians married, he was doubtless normal enough to have procreated, and that his sterility did not set in until his twenties or thirties.

Furthermore, artists have represented Akhnaton as normal in his teens but later as androgynous rather than wholly masculine: with a large head on a long thin neck, a receding forehead, a drooping chin, narrow shoulders, slim arms and legs, wide hips, and full breasts. Facially, some of his statues present either a fixed stare or a vacant smile.

To supplement evidence from the dead antiquity of remains and the static imagery of art one can turn to the more dramatic testimony of historical fiction. In Dmitri Merezhkovsky's "Akhnaton, King of Egypt" one can observe the man alive, during the most revolutionary and fateful years of his reign. His character appears highly admirable, his outlook humanistic, his objectives altruistic, and his devotion to those he loved warm and constant.

But unfortunately his insidious malady marred his private life and public career. Under the stress of excitement he became unstable and had occasional epileptic fits, "the sacred illness," so-called because it was thought to indicate possession by a god. He humbly considered himself stupid and deplored his forgetfulness. Sometimes he appeared to be in a trance; then again he became delirious and laughed and cried and sang.

Akhnaton was not the only historic personage so afflicted; other sovereigns were likewise visited by etiologically obscure disorders. Due to the practice of royal inbreeding, various hereditary diseases and defects have not been as rare in the annals of history as might be supposed. A full assessment of the impact of the morbidities of early monarchs might well clarify some of the more inscrutable aspects of their power-policies — not only politically and economically, but culturally and spiritually as well.

The field is wide open to the medico-historian.

There's a Difference

Actually there's only a slight difference between keeping your chin up and sticking your neck out, but it's a difference worth knowing. — News, Milford, Mass.

Child Psychiatry

Placement of Mentally Retarded Children Home or Institution?

For many years, planning for mentally retarded children frequently has raised the issue of whether or not a child should be placed out of the home for some form of care, education, or treatment. At times the issue has been one of whether or not the family can survive the strain of caring for a retarded child, who may present difficult management problems, or require complex nursing care. Occasionally the presence of a high degree of community pressure in the form of isolating or stigmatizing the family of the retarded child may be a factor.

Until recent years, when placement of a child out of the home has been deemed necessary for whatever reasons, the chief resource has been the state institutions for the retarded. Presently, however, in addition to the state schools and hospitals, there also exists a large array of facilities, including boarding homes, specialized private nonprofit institutions, and modified nursing homes. The actuality of the need for placement has been modified by the development of special education classes in the public schools for "educable" and "trainable" retarded children, and also, more recently by the establishment of privately operated state-subsidized Day Activity Centers.

The Minnesota State Department of Public Welfare has been directly or indirectly involved in the development of many of these facilities and programs. The direction of the state schools and hospitals is a responsibility of the Welfare Department Medical Services Division. The Medical Services Division's Section on Mental Retardation and Epilepsy discharges the responsibilities of the Commissioner of Public Welfare for persons committed to his care as mentally retarded. The Child Welfare Division is responsible for the standards and licensing of private institutions, foster homes, and Day Activity Centers for mentally retarded persons.

As awareness has increased of the enormous variety of medical, psychological, and social needs of mentally retarded children and their families, and as facilities have developed in response to these needs, decisions about care, education, and treatment have become extremely difficult to make. In an effort to provide some guidelines toward making these decisions, the Department of Public Welfare has issued a policy statement based on a few fundamental principles which may be expressed as follows:

1. Separation of a retarded child from his parents is an extremely serious decision with respect to the well-being of both child and parents.
2. Minimizing the effects of this often traumatic experience requires skillful and time-consuming work on the part of the family physician, pediatrician, and social case worker.
3. The decision to place a child out of the home should be a joint one, involving the parents, the family physician, and the case worker.

Continued

4. The determination of what facility to use should be based on a thorough medical, psychological, and social work study of the child and family, and a knowledge of the variety of facilities available to the child and family. This often requires the combined efforts of the pediatrician, psychiatrist, psychologist, social worker, and public health nurse.
5. If the child must be removed from his home, he should be placed in the facility closest to his home that can meet his needs.

The policies based on these principles are stated in a bulletin issued by the Commissioner of Public Welfare on July 26, 1965, as follows:

"1. No child should be considered for placement out of the home without a comprehensive evaluation not only of the afflicted child but also of the family and community resources. Ideally such an evaluation is coordinated and multi-disciplinary and includes pediatric, psychological, social, and psychiatric studies. Mental health centers, the Child Development Centers at Fergus Falls and Owatonna, the services of the University of Minnesota, and services still in the development stage can be utilized for this purpose, as can purchase of locally available service.

"2. Commitment to guardianship as mentally deficient is not a necessary or desirable step in all cases. A non-committed person is entitled to the same services as a person under guardianship. A person need not be committed as a prerequisite to admission to a state institution for mentally retarded. If commitment is desirable, it can be done at any time in the retarded person's life and need not be done when the retardation is first discovered.

"3. A final decision on placement should not be made until the parents have been told of the variety of facilities and services available and given the maximum opportunity to consider their feelings both about caring for their child who is retarded and about possible separation for shorter or longer periods of time. When separation is necessary in order to resolve a crisis, or to provide adequate nursing care or supervision, placement should be in a facility as close to home as possible to allow frequent contact between parent and child. Placement should not be considered as a permanent step.

"4. In an instance in which placement outside the home is urged that is considered inappropriate by the county welfare agency, such a placement should be discouraged until reasonable case work effort has been made to help the parents completely assess their situation. In some instances, a temporary placement may be necessary while case work continues. If the parents continue to insist on a long-term placement, a foster home placement is more desirable than institutional placement.

"5. Case planning for the retarded should be done as much as possible at the local level among those agencies that will be dealing directly with the person."

Each of these policies has a direct relationship to the general practitioner or pediatrician when he suspects or diagnoses mental retardation. The role that the physician takes under these circumstances may affect the entire family positively or negatively for many years.* The information about developments in the area of mental retardation has reached various professional groups slowly and unevenly. Parents, therefore, often are demoralized by contradictory statements from physicians, psychologists, and welfare workers even within their own communities regarding the desirability of institutional placement.

For example, until recently Down's syndrome (Mongolism) when discovered at birth has been understood to be adequate basis to insist that the afflicted child be placed in an institution immediately. Studies of such children, however, reveal that given the stimulus of parental relationships they may be capable of considerably more mental and emotional development than heretofore was realized. Although residential care may become necessary at a later age, the possibility of a more constructive adjustment is greatly increased if the child spends its early years in its own home. In the case of Down's syndrome, then, parents may be advised by the physician who delivered their child to apply for admission to an institution for the mentally retarded immediately. On contacting their county welfare agency, however, they may be told that such children will not be considered for admission until they are much older. From this point on, whoever they see may be unwittingly placed in the position of passing a judgment on the two advisors, but nothing that he says may really resolve the uncertainty of the parents. More subtle degrees of mental retardation or mental retardation in association with behavior problems in older children often make for even more complicated and difficult decisions in which the advice of the family physician may be relied upon heavily.

Few physicians are likely to have the time to remain familiar with all developments in the field of mental retardation or to organize personally a total evaluation and treatment program for their mentally retarded patients. Available to the physician, however, are the assistance of the county welfare departments, community mental health centers, the staffs of the nearest institution for the mentally retarded, the local public health nurse, the resources of the State Department of Public Welfare, and the resources both state and local of the Associations for Retarded Children. The latter organizations contain many parents who may be particularly helpful because they have successfully faced the problems associated with having mentally retarded children.

This article is intended primarily to alert the physicians of Minnesota to these Departments of Public Welfare policies and underlying philosophy. Questions which these policies raise that are not answered in the article should be directed to the Medical Services Division of the Department of Public Welfare, where they will be welcomed and responded to immediately.

Richard E. Bartman, M.D.**

Ours is an age which is proud of machines that think, and suspicious of any man who tries to. — Howard Mumford Jones

Photographic Contest

The Editors of MINNESOTA MEDICINE, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in MINNESOTA MEDICINE.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼", can be considered.
4. Each slide should be labeled with the maker's name, address, and the identifying title.
5. Slides should not be mounted on glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in MINNESOTA MEDICINE in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of MINNESOTA MEDICINE and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of MINNESOTA MEDICINE and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

Announcing

EUTRON™

pargyline hydrochloride 25 mg. and methyclothiazide 5 mg.

for control of
moderate to severe
hypertension

Unique combination produces greater antihypertensive effect with lower doses

Eutron is the combination in a single tablet of 25 mg. Eutonyl (pargyline hydrochloride) and 5 mg. Enduron (methyclothiazide). This combination produces greater therapeutic effect than that of either component used alone. Side effects may be milder, too, as dosages are generally lower. The effective dosage is usually one tablet, once daily. Tablets are scored for greater dosage flexibility.

EUTONYL
25 mg. PARGYLINE HYDRO CHLORIDE
Caution: Federal (U.S.A.) law prohibits dispensing without prescription.
100 No. 6812
Tablets (Grooved)
ENDURON
METHYCLOTHIAZIDE
Caution: Federal (U.S.A.) law prohibits dispensing without prescription.

Each Eutron tablet contains two proven antihypertensives in the ratio shown to be most effective in most patients.

TM—TRADEMARK

New **EUTRON** extends your range of treatment in moderate to severe hypertension

A single product you can use even in the presence of congestive heart failure or edema

Eight out of 10 patients respond

In clinical trials, Eutron produced normotension or a significant reduction in blood pressure in eight out of 10 patients studied. The rationale for the product is this: Eutonyl used alone is a potent antihypertensive. Its antihypertensive action is markedly enhanced by Enduron, a potassium-sparing thiazide.[1,2,3] The combination (Eutron) thus produces greater antihypertensive effect with lower dosages of the Eutonyl component, and milder side effects may be seen.

3. Bryant, J. M. et al., Antihypertensive Properties of Pargyline Hydrochloride, New Non-Hydrazine Monoamine Oxidase Inhibitor Compared with Sulphonamide Diuretics, J.A.M.A., 178; 406, Oct., 1961.

BP reductions in the recumbent and sitting positions often are nearly as great as in the standing. In clinical trials, the average *recumbent* BP reduction was 36/18 mm. Hg.

The average *standing* reduction in clinical trials was 45/22 mm. Hg. Thus the difference between the standing and recumbent readings was only 9/4 mm. Hg.

Significantly lowers blood pressure in all body positions; less likelihood of orthostatic hypotension

In clinical trials, the average reduction in standing blood pressure was 45/22 mm. Hg.; in the sitting position it was 48/20 mm. Hg.; and in the recumbent position, 36/18 mm. Hg.

Because Eutron effectively reduces blood pressure in all body positions, there is reduced likelihood of orthostatic symptoms or hypotension.

This was reflected in the relatively mild character of side effects seen in clinical trials (see below).

Smooth and gradual onset

Onset of antihypertensive action is usually quite smooth. Initial reduction of systolic and diastolic readings is usually seen within a week – maximum reduction in seven to ten days.

Less troublesome side effects may be seen; frequent improvement in "sense of well-being"

Fewer than 1% of patients studied discontinued Eutron therapy because of side effects. This is due in part to the relatively low dosage needed with the combination. Usual recommended dose is one tablet daily—that is, 25 mg. Eutonyl with 5 mg. Enduron. *This is about half the usual therapeutic dose of Eutonyl given alone.* As a consequence side effects may be milder. And, as with Eutonyl given alone, the patient may well note an increased sense of well being. This is in distinct contrast to most other antihypertensive therapy.

ABBOTT

Prescribing information for **EUTRON**

INDICATIONS: Eutron (pargyline hydrochloride and methyclothiazide) is indicated in the treatment of patients with moderate to severe hypertension, especially those with severe diastolic hypertension. It is not recommended for use in patients with mild or labile hypertension amenable to therapy with sedatives and/or thiazide diuretics alone.

CONTRAINDICATIONS: Eutron is contraindicated in patients with pheochromocytoma, advanced renal disease, paranoid schizophrenia and hyperthyroidism. Until further experience is gained it cannot be recommended for use in patients with malignant hypertension, children (under 12 years of age), or pregnant patients.

The concomitant use of the following is contraindicated: other monoamine oxidase inhibitors; parenteral forms of reserpine or guanethidine; sympathomimetic drugs; foods high in tyramine such as cheese; imipramine and amitriptyline, or similar antidepressants; methyldopa. A drug-free interval of two weeks should separate therapy and use of these agents.

WARNINGS: Pargyline hydrochloride is a monoamine oxidase inhibitor. Patients should be warned against eating cheese, and using alcohol, proprietary drugs or other medication without the knowledge of the physician. When it is necessary to administer alcohol, narcotics (notably meperidine), antihistamines, anesthetics, barbiturates and other hypnotics, sedatives, tranquilizers, or caffeine, these agents can be used cautiously at a dosage of ¼ to ⅕ the usual amount. Avoid parenteral administration where possible. Withdraw pargyline two weeks before elective surgery.

Patients should be warned about the possibility of postural orthostatic hypotension. Those with angina or other evidence of coronary disease should not increase physical activity. Pargyline may lower blood sugar. Potassium depletion is unlikely at the recommended dosage, but if it occurs, adjust dosage or withdraw or provide added natural food sources of potassium; potassium tablets should be avoided wherever possible, as bleeding or obstructive ulceration of the small bowel has been associated with their use; potassium levels should be especially watched if the patient is on digitalis or steroids, or if hepatic coma is impending.

PRECAUTIONS: When determining the antihypertensive effect of Eutron, blood pressure should be measured while the patient is *standing*. Use with caution in hyperactive or hyperexcitable persons. Such persons may show increased restlessness and agitation. Withdraw drug during acute febrile illness. Watch patients with impaired renal function for increasing drug effects or elevation of BUN and other evidence of progressive renal failure; withdraw drug if such alterations persist and progress. Pargyline has not been shown to cause damage to body organs or systems. As with all new drugs, complete blood counts, urinalyses, and liver function tests should be performed periodically. The drug should be used with caution in patients with liver dysfunction. With prolonged therapy, examine patients for change in color perception, visual fields, and fundi.

Elevated blood urea nitrogen, serum uric acid or blood sugar are possibilities attributable to the methyclothiazide in Eutron. Methyclothiazide may also reduce arterial response to pressor amines. Blood dyscrasias, including thrombocytopemia with purpura, agranulocytosis and aplastic anemia, have been seen with thiazide drugs.

SIDE EFFECTS: The use of pargyline may be associated with orthostatic hypotension. Mild constipation, slight edema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence, delayed ejaculation, rash, and purpura have been encountered with pargyline. Hyperexcitability, increased neuromuscular activity (muscle twitching) and other extra-pyramidal symptoms have been reported. Drug fever is extremely rare. Congestive heart failure has been reported in a few patients with reduced cardiac reserve. Nocturia has been observed with the combination. If side effects persist, despite symptomatic therapy or reduction of the dose, discontinue the drug.

Clinical Path Conference

Quadriplegia in a Patient on Anticoagulant Therapy

A 51-year-old married white male engineer was admitted to St. Barnabas Hospital on September 12, 1964, with a four-day history of intermittent chest pain. The pain was more severe with each attack, radiating to the back and both shoulders, and was accompanied by nausea and vomiting. In 1956, he had a myocardial infarction, and in December, 1962, he suffered a second infarction. He was placed on bisoxycoumarin (dicumarol) therapy, which was continued until his final admission. A duodenal ulcer was first demonstrated in 1957 and was seen again on x-ray during his 1962 admission. His gallbladder had been removed in 1944.

Physical Findings

He was obese and apprehensive but not dyspneic. The blood pressure was 130/80, the pulse 94 and regular, and the temperature 99°F. The neck veins were not engorged. Heart tones were good with a normal rate and rhythm. The chest was clear; no rales or abnormal breath sounds were heard. A healed scar was present below the right costal margin. The liver and spleen were not palpable. No peripheral edema was observed. The admitting diagnosis was coronary insufficiency with impending myocardial infarction.

Laboratory Studies

The admission laboratory work included a hemoglobin of 14.7 gm.% and a white blood cell count of 12,000 with 80 polymorphonuclear leucocytes and 12 band forms. The urinalysis showed a pH of 6.5, a specific gravity of 1.017, and 40-50 red cells per high-power field. A prothrombin time on September 14 was 39 seconds (control 12.2 seconds) and on September 15, 25 seconds (control 12.9 seconds). The serum glutamic transaminase for the first three days of hospitalization was 28 units, 49 units, and 56 units (normal 4-40 units). Electrocardiographic changes indicated a healed anterior myocardial infarction. The chest x-ray was normal.

Progression of Symptoms

On the second day the patient experienced muscle pain in the neck and shoulder, which increased with movement. The muscles were tender to palpation. Ecchymoses of the skin were observed. On the fourth day he suddenly developed generalized weakness and was unable to move his legs or lift his arms. Neurological examination disclosed diffuse tenderness over the posterior neck and shoulder, a right sixth nerve paresis, extreme weakness of the sternocleidomastoid, deltoid, and triceps muscles, total flaccid paraplegia, areflexia, and bilateral absence of pain, temperature, and touch below C-5. The intercostal muscles barely moved. His breathing was diaphragmatic. Cough and swallowing were poor.

On September 16 a lumbar puncture was done. The opening pressure was 120 mm. of water, and the fluid showed a protein of 4680 mg./100 ml., 14,750 RBCs/mm.^{3}, and 81 WBCs/mm.^{3}. A tracheostomy was performed. Laboratory studies completed the following morning included a hemoglobin of 12.0 gm.%, a WBC of 10,200/mm.^{3}, normal blood urea nitrogen and serum electrolytes, and a prothrombin time of 14.5 seconds (control 12.7 seconds).

Late in the afternoon of September 17, he complained of excruciating pain in the posterior neck. A lumbar puncture was repeated; the Queckenstedt maneuver was

Continued

normal; a myelogram was performed. Later that evening, the patient was taken to the operating room where an emergency cervical laminectomy was performed.

Lawrence Farber, M.D.:*

The case for today is a 51-year-old married white male engineer with a four-day history of intermittent chest pain, accompanied by nausea and vomiting. Eight and two years previously he had a well documented myocardial infarction. He was placed on dicumarol therapy after the second episode. He has a seven-year history of a duodenal ulcer.

The History

Let us consider the history — the most important part of diagnosis in medicine. We have an individual with two preceding myocardial infarctions, and I assume that chest discomfort had been present. He complains of intermittent chest pain, radiating into the back and both shoulders. The pain is associated with nausea and vomiting, a common occurrence with myocardial infarction.

It is known that he had a duodenal ulcer. With pain radiating into the back and between the shoulder blades, and even chest pain, a perforating ulcer must be considered. Other considerations are pulmonary emboli, infectious processes, dissecting abdominal aneurysm of the aorta, acute pancreatitis, and liver disease.

The Physical Examination

With a blood pressure of 130/80, a pulse of 94, a clear chest, and no engorged neck veins, an extensive myocardial infarction is unlikely. No evidence of severe myocardial failure exists, though impending myocardial infarction is possible.

The admission white blood cell count was 12,000 with 80 polys and 12 band forms. The urine showed 50 red cells per high-powered field, probably resulting from anticoagulants, though the prothrombin time on September 14 was only 39 seconds (control 12.2 seconds). On September 25 the prothrombin time was 25 seconds (control 12.9 seconds). Three days after admission, his prothrombin time was still very high. What his prothrombin times were on the outside and whether these determinations represented a recent rise in the prothrombin time are not known. The electrocardiogram revealed a healed anterior myocardial infarction; there were no acute changes.

Course in Hospital

On the second day he had pain and tenderness of the muscles of the neck and shoulder. Ecchymoses of the skin were observed. On the fourth day he suddenly developed generalized weakness and was unable to move his legs or lift his arms. Four days after his admission he developed quadraparesis. Neurological examination disclosed diffuse tenderness over the posterior neck and the shoulders, a right sixth nerve paresis, extreme weakness of the sternocleidomastoid, the deltoid, and triceps muscles, a flaccid paraplegia, areflexia, and absence of the intercostal respiration.

---

*Attending Neurologist, St. Barnabas Hospital.

Differential Diagnosis

Mid-Cervical Lesion

He was evidently breathing with his diaphragm which receives innervation from C3, C4, and C5, as we know that his intercostal muscles, which are thoracically innervated, were out. His triceps muscles, which derive their innervation from the seventh and eighth cervical nerve roots, were very weak. The deltoid muscles, which receive innervation from the fifth and sixth nerve roots, were also weak. The biceps muscles were not mentioned. The sensory level is about C5. The lesion, whatever it is, is in the mid and lower cervical region. The severe weakness of the sternocleidomastoid muscles suggests derangement of the eleventh cranial nerve, the third cervical nerve, and possibly the fourth. The difficulty with swallowing and cough suggests vagus nerve involvement. A right sixth cranial nerve paresis is present.

Extensive Cord Involvement

We have extensive spinal cord involvement; in addition, we have patchy lower cranial nerve involvement and muscle tenderness and pain. I see nothing about radicular pain radiating down the arms or legs.

On September 16, a lumbar puncture revealed the pressure to be 120 mm. of water — a normal pressure. The fluid showed a protein of 4,680 mg., 14,750 RBC and 81 WBC. This is indeed a very, very high spinal fluid protein. Froin's syndrome* — resulting from a total or partial spinal column block — is the only condition reported with proteins of four, five, and six grams.

An emergency tracheostomy was performed because of further respiratory difficulty, to provide more effective pulmonary toilet and to facilitate the use of the Bird or Bennett Respirators.

Laboratory studies completed the following morning revealed a prothrombin time of 14.5 seconds and a control of 12.7 seconds. This is within the normal range. Late in the afternoon on September 17, five days after admission, he complained of excruciating pain in the posterior neck. A spinal tap was repeated; the Queckenstedt maneuver was normal; a myelogram was performed.

Lesions Causing Cord Transection

Few things will cause such an acute process to develop. Because of the severe but focal neurological signs, one has to consider local lesions causing spinal cord transection. Excessive anticoagulation must be considered. Hematomyelia (bleeding into the spinal cord) or intradural or epidural hematoma may have caused acute, severe spinal cord compression and a transection syndrome. Expansion of a tumor of the lower cervical cord enters into the diagnosis. A person on anticoagulants could have hemorrhaged into a metastatic neoplasm or a primary tumor of the spinal cord. A vertebral body with metastatic tumor or extensive osteoporosis could have collapsed to cause the cord compression.

Guillain-Barre Syndrome

In addition to the cord lesion, the sixth, tenth, and twelfth cranial nerves were involved. Polyneuritis can come on acutely. The cardinal signs and

---

*See Page 152.

Continued

symptoms of Guillain-Barre syndrome include muscle tenderness and radicular pain. Its course can be either acute or chronic. Recently we saw a 16-year-old girl who developed a quadriplegia and total loss of respiratory ability within three or four hours. Besides peripheral nerve involvement, there may be deep muscle tenderness and radicular pain, weakness, numbness; the spinal cord, cranial nerves, and at times even the brain can be affected. A polyneuropathy in the presence of a bleeding tendency is, of course, possible.

The exceedingly high spinal fluid protein — almost 5 grams/100 ml. — probably eliminates polyneuritis as the primary process. The high protein is more likely in the partial or total block. The Queckenstedt was negative, but this is not significant, as even a pin-sized hole can provide a normal variance in pressure during the Queckenstedt maneuver. I assume this high protein results from the partial or almost total spinal fluid block. Perhaps the radiologist can tell us more about the nature of the block.

Dr. Philip Olson*

A cervical myelogram performed on September 17 revealed a complete block to the flow of panopaque at the level of the disc space between C6-C7. A trickle of panopaque is attempting to go along the right lateral aspect of the lower cervical spine. It should be immediately adjacent to the bone, but here it is elevated. This would indicate a space-occupying lesion in the lower cervical area, located anteriorly and displacing the column posteriorly.

Dr. Lawrence Farber

Does this look like intramedullary or extramedullary bleeding?

Dr. Philip Olson

Since the panopaque is displaced posteriorly, an extradural lesion is more likely. It could be interpreted as intramedullary on the basis of the posteroanterior films, but the lateral film indicates an extradural location.

Dr. Lawrence Farber

Now we know the lesion is probably extradural. A hemorrhagic process seems to be the most logical diagnosis. It would be foolish to ignore the high prothrombin time in the face of blood in the urine and in the skin. Bleeding may be the reason for the compression of the spinal cord. Therefore, we may be dealing here with an extradural hematoma anterior to the spinal cord causing a transection syndrome in the lower cervical area with a clinical quadriplegia. It is difficult to explain the cranial nerve involvement, particularly the tenth, eleventh, and right sixth nerves, except on the basis that more extensive hemorrhage has taken place. Brain stem hemorrhages could account for the dysphagia, particularly with hemorrhages in and around the nucleus ambiguous. Other entities such as tumor with hemorrhage must be considered. An infectious process is not likely.

Dr. Lawrence Farber's Diagnoses:

1. Epidural hemorrhage of cervical spinal cord secondary to dicumarol

---

*Radiologist, St. Barnabas Hospital.

therapy.

2. Focal hemorrhage into brain with involvement of sixth, tenth, and eleventh cranial nerves.
3. Coronary sclerosis with old myocardial infarction.

Dr. Donald Mac Kinnon

I believe anticoagulant bleeding may be the answer. Strange complications can occur. About ten days ago we saw a lady with an acute abdomen. She was thought to have an appendicitis. She gave a history of taking birth-control pills for several years and had a recent thrombophlebitis of the leg five weeks before I saw her. She was put on dicumarol for the thrombophlebitis and was in the hospital for about ten days. She had recently had a prothrombin time in the therapeutic range, but a repeat prothrombin time revealed 71 seconds. She was given Mephyton. The next day her abdominal symptoms and signs had disappeared. We cannot substantiate dicumarol bleeding, but it is a plausible explanation for her symptoms and course. Two drugs may have caused her malady: the birth-control pills and the dicumarol.

Dr. Carl O. Rice

The usual complications occurring with dicumarol are ecchymoses, bleeding from the kidney, and hematuria; but it is the unusual ones that disturb us. A year ago I had a patient with an acute abdomen. Distention and melena without massive hemorrhage were observed for a few days without any improvement in the symptoms. She had been on dicumarol, and the prothrombin time was about 29 seconds (normal 14). The bleeding symptoms persisted despite repeated tranfusions.

At exploration we found the mesentery of the entire gut swollen and edematous, with patches of ecchymosis scattered throughout. In the wall of the gut we saw intramural hemorrhage; within the lumen of the gut we saw larger patches of melena. Subsequently she was given Vitamin K and made a satisfactory recovery.

The coagulation scheme is complex and spontaneous bleeding can occur if a deficiency exists in any of the coagulation stages or with an excess of anticoagulant. The prothrombin time can be altered by fever, salicylates, liver disease, or a number of other conditions. The muscle tenderness which was observed could be due to extravasation of blood into the muscles.

In this patient, Dr. Farber, the operation was indicated because of the nature of the cord transection and the possibility of relieving the compression. I would expect on the basis of the cranial nerve findings that there were additional hemorrhages higher, in the brain stem.

Dr. Lawrence Farber

Complications of anticoagulant therapy occur in all realms of neurology. Subarachnoid or epidural hemorrhage occasionally happens. Intracerebral hemorrhages in the area of the basal ganglia or temporal lobe are frequently reported, occurring most often in association with straining and heavy lifting. Anticoagulants can be a two-edged sword and in this patient the hemorrhage was catastrophic, resulting in over-anticoagulation. The high protein concentration in the spinal fluid, in spinal block, almost as

Continued

high as in the blood stream, is not thoroughly understood. Stagnation occurs. Much of the protein, particularly if it is in the presence of a tumor, would come from the surrounding tissue itself. Water is drawn out; protein is not. These physiologic mechanisms create the elevated protein.

Dr. Richard Reece

As a rule, for every 1,000 RBC there is a 3 mgm. rise in protein. With 15,000 red cells, a rise of 45 mg. per 100 ml. would result. This falls far short of the 4750 mg. elevation in this patient.

Dr. Lyle Hay*

The protein elevation of the spinal fluid is due to extradural hemorrhage which in turn caused the block. It is not merely the presence of blood in the spinal canal.

Pathological Discussion

Dr. Richard Reece**

I omitted this patient's course after laminectomy in order to concentrate on the nervous system. After the laminectomy, the dura was left open for decompression. One day later he developed a distended abdomen, was operated on, and a perforated ulcer was found. He died shortly after operation. At autopsy the principal gross findings were a large organized anterior epidural hematoma and diffuse peritonitis.

Dr. J. Popowich

We removed the cord from the posterior approach. The hematoma extended from the third cervical vertebra to the lumbar area. The cervical cord was compressed and flattened. Microscopically, extensive degeneration and necrosis were observed in the anterior cord adjacent to the hematoma. In Guillain-Barre disease the changes usually occur in the posterior columns and sometimes are associated with demyelinization and chronic inflammation around the dorsal root.

Dr. Richard Reece

There was no other hemorrhage within the body. In the brain, I saw focal encephalomalacia, a change which, I suppose, could be secondary to a polyneuritis. Guillain-Barre syndrome is hard to document in its acute stages. At two days, only edema is seen; at one week, necrosis and degeneration, and at nine days, perivascular lymphocytic reaction around the dorsal roots. After looking at all the slides, I cannot make the diagnosis or exclude it. Other findings included an old anterior myocardial infarction with a sclerosis of his anterior descending coronary artery. He had diffuse peritonitis from the perforated ulcer.

The Dilemma

Spurney and his group in Kansas City reported two cases of epidural hematomas with anticoagulants and found eight in the literature.[1] Thirty-five patients with spontaneous hemorrhage had not received anticoagulant

---

*Director of Medical Education, St. Barnabas and Swedish Hospitals.
**Pathologist, St. Barnabas Hospital.

therapy. Eight of the ten patients on anticoagulants had prothrombin times within the normal therapeutic range.

There are fifteen reported cases of "spontaneous" subdural hematomas. In eight the prothrombin times were in the normal range.[2] Even if the clinician treats the patient appropriately and the prothrombin times are within the therapeutic range, the patient still may bleed. Despite this dilemma it is the general feeling that the good aspects of anticoagulant therapy outweigh the bad. An unquestioned benefit occurs with treatment of thrombophlebitis. However, there is some controversy about anticoagulant therapy in people with coronary artery disease.[3] In general, prophylactic anticoagulation has been abandoned for cerebrovascular sclerosis or thrombosis.

Bleeding in the Therapeutic Range

Why do patients bleed in the therapeutic range? Many are subsequently proven to have an underlying disease.[4] This is particularly true in the gastrointestinal tract. Bleeding in the normal range should initiate a search for an organic lesion.

Owren of Scandanavia states that the Quick prothrombin time is not sensitive enough to detect the Factor X.[5] He claims that the use of thromboplastins insensitive to Factor X are the most frequent cause of bleeding during anticoagulant therapy. He developed a test, Thrombotest, with a high sensitivity to Factor X.[6] Another problem confronting the clinician is the difference between laboratories as to how prothrombin times are reported — per cent, ratios, and seconds — with resulting confusion.[7]

Bizarre Complications with Anticoagulants

The lesson here is to look for bizarre complications in a patient on anticoagulants. One is *adrenal hemorrhage* with acute adrenal insufficiency. These patients experience nonspecific abdominal pain, ileus, and high fever. This complication is usually unrecognized. Fourteen cases have been reported.[8] A second complication is a rapidly enlarging *pericardial effusion*.[9] These patients did not have myocardial infarcts, but still bled into the pericardial cavity. Other complications are *necrosis of the skin, gangrene of the breasts, hemorrhagic pancreatitis,* and a curious lesion known as the *"Purple Toe Syndrome."*[10-13] There was a recent case report of *hemorrhage into a pituitary adenoma,* with deiplopia and subsequent death.[14] As Doctors Rice and MacKinnon have mentioned, there have also been reports of small and large bowel obstruction, secondary to bleeding into the intestinal wall.[15,16]

I have performed an autopsy on a man who went blind during a bowel movement. He was on long term anticoagulation therapy. His prothrombin time was 34 seconds. He had a "spontaneous" subdural hemorrhage at necropsy.

Probably the most tragic cases are *fatal hemorrhage in infants* whose mothers are on anticoagulants.[17]

Strange complications can occur in patients on anticoagulation therapy. I sympathize with the clinicians. They are on a fulcrum; on the one side they face the deadly threat of thrombosis and on the other the ominous consequences of hemorrhage. We can never fully realize the potentialities of the drugs we use. In New Haven it was found that 20 per cent of

Continued

hospitalized patients suffered adverse effects from diagnostic and therapeutic agents or procedures.[19] Bleeding as a complication of anticoagulant therapy occurs in about 10 per cent of hospitalized patients and in about 40 per cent of ambulatory patients.[18] We can standardize drugs and perfect techniques, but we cannot standardize people.

Dr. Lawrence Farber

Epidural hematomas of the spinal cord occur in other situations than in the presence of anticoagulation therapy. In the last three years we have had two instances of epidural hematoma occurring within a day of laminectomy. Fortunately these were found in time and decompressed. A most curious case was that of a man with a past history of tuberculosis and diabetes who had a transection syndrome three weeks after a whiplash injury. He had not been on anticoagulants but at operation was found to have a spontaneous epidural hematoma. This could have been secondary to vascular malformations of the vertebral body or to the preceding trauma.

Anatomical Diagnosis

1. *Organizing anterior epidural hematoma (probably secondary to dicumarol therapy) with degeneration and necrosis of anterior portion of the spinal cord.*
2. *Duodenal ulcer with rupture and diffuse peritonitis.*
3. *Severe coronary artery sclerosis with old myocardial infarction.*
4. *Focal encephalomalacia of the brain.*

FROIN'S SYNDROME

The massive coagulation-xanthochromic syndrome originally described by Froin refers to an increased amount of exudative products found in the spinal fluid below the level of a partial or complete block of the spinal canal. The high protein level of the spinal fluid has been attributed to spinal cord tumor. There is a flaccid or spastic paraplesia, sensory and sphincter disturbances, and in some instances subjective pain is evident. The neurologic disturbances depend upon the level of the block, which usually is observed in the lumbar region.

The spinal fluid undergoes spontaneous coagulation and is found to contain a large amount of globulin with a high total of protein. Xanthocromia is evident and there is a decrease in spinal fluid pressure with no elevation on coughing.

This condition is found in secondary neoplasms, Pott's disease, Landry's paralysis, serous or tuberculous meningitis, meningomyelitis, and pachymeningitis.

If the underlying pathology is benign, laminectomy and decompression may afford favorable prognosis.

Grand Rounds

Traumatic Aortic Aneurysm

When an individual sustains thoracic injury of such a magnitude as to tear the aorta, the consequence is generally immediate death from hemorrhage.[1] However, the aortic rupture may be confined to a hematoma within the mediastinum, and the diagnosis of traumatic aneurysm of the thoracic aorta may be made some time later.[2] After such a post-traumatic aneurysm has been detected, the patient should be evaluated for operative repair.

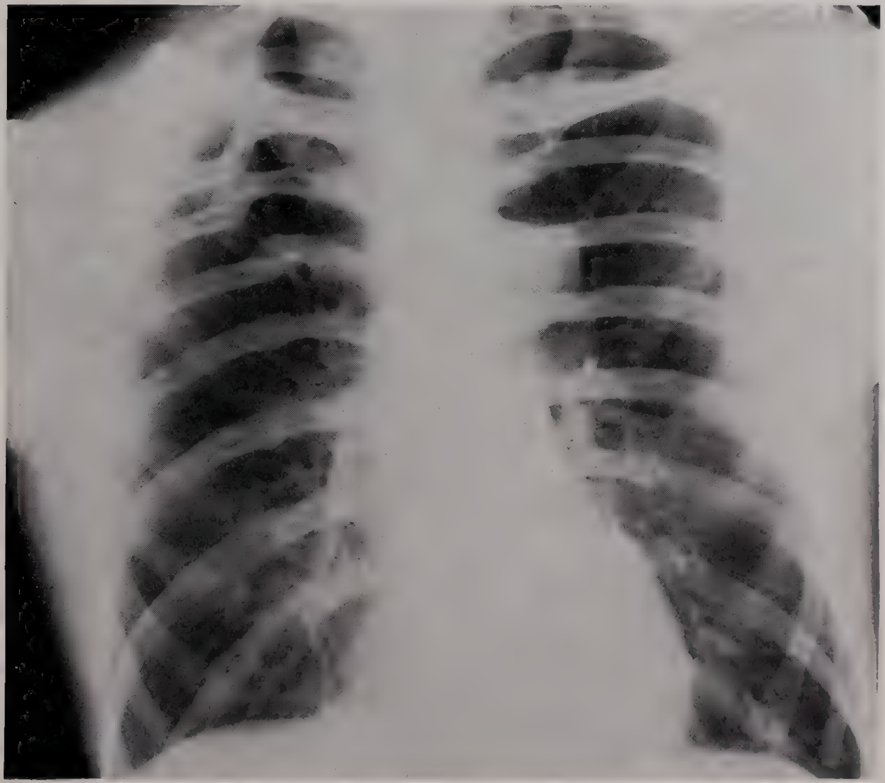

Fig. 1 — Routine chest x-ray (Case 1).

Continued

Case Report

A twenty-nine-year-old white male was admitted to the Dearborn Veterans Hospital on April 17, 1964, with lower back pain resulting from an automobile accident that occurred November 11, 1963. While making a left turn, his car was struck by two other automobiles, pinning him between the steering wheel and the front seat. He was immediately hospitalized and found to have a fractured right clavicle, multiple rib fractures, fracture of the lumbar vertebra, a right hemopneumothorax, a laceration of the right lobe of the liver, and rupture of the right kidney.

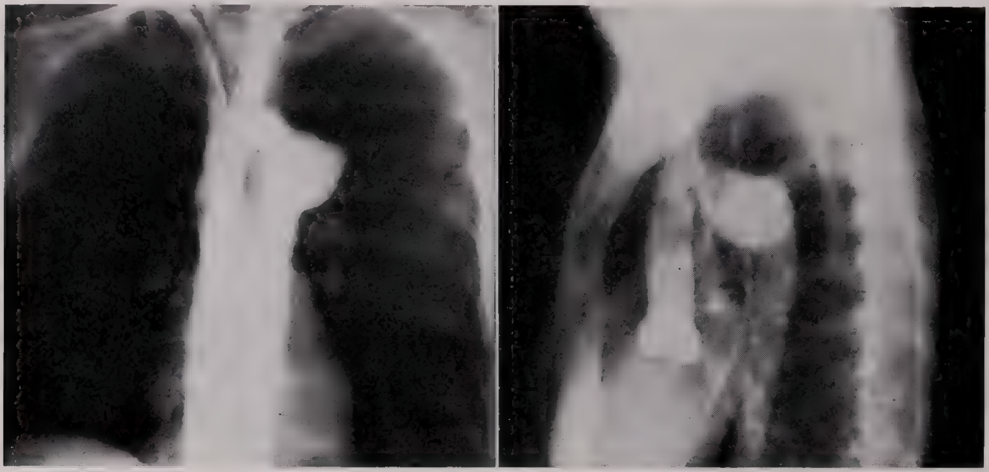
Shortly after admission he underwent right nephrectomy and repair of the liver injury. Postoperatively, because of renal failure, dialysis was required. After renal function returned and the fractured clavicle had been repaired, the patient was eventually discharged in March 1964. When seen at our hospital, he denied cardiorespiratory symptoms. His past history was not contributory.

Physical Examination

Physical examination revealed the blood pressure to be 110/80 mm. Hg. in both arms and 130/100 in both legs. The pulse was regular and no heart murmurs were present. There was a deformity of the right clavicle. Minimal tenderness was present over the lower lumbar vertebrae, but there were no reflex, motor or sensory changes in the lower extremities. The electrocardiogram was normal and the laboratory work otherwise noncontributory.

X-ray Findings

X-rays of the lumbosacral spine showed post-traumatic changes of the fifth lumbar vertebra. The chest x-ray was interpreted as showing, in addition to healed fractures of the right third through tenth ribs posteriorly, an unusual expansion of the aortic knob (Figure 1). A retrograde aortogram demonstrated a saccular aneurysm, 5 cm. in greatest diameter, arising in the descending aorta 3 cm. distal to the subclavian artery (Figures 2a and 2b).



Figs. 2 (a-left) and (b-right) — Retrograde aortogram (Case 1).

Operation

No specific treatment was recommended for the patient's back. Surgical treatment of the aneurysm was decided upon and accomplished on June 3, 1964. The right brachial artery pressure was monitored. The left chest was entered through the bed of the fourth rib. A 4 x 6 cm. aneurysm of the descending aorta was separated from adherent lung, pulmonary artery, and esophagus. Blood was shunted from the left atrium to the left femoral artery at a rate of 1200 cc./min. during a 30-minute period while the aorta was occluded proximal to the origin of the left subclavian artery and again distal to the aneurysm. After the aneurysm had been entered, it became apparent that the aortic wall had been torn transversely for about ¾ of its circumference (Figure 3). A two-inch segment of aorta containing the aneurysm was resected and replaced with a Teflon graft. The postoperative course was uneventful and the patient was discharged on the twenty-first postoperative day (Figure 4). He remains well and has returned to normal activity.

Discussion

Symptoms

Many patients with chronic aortic aneurysms after trauma have no

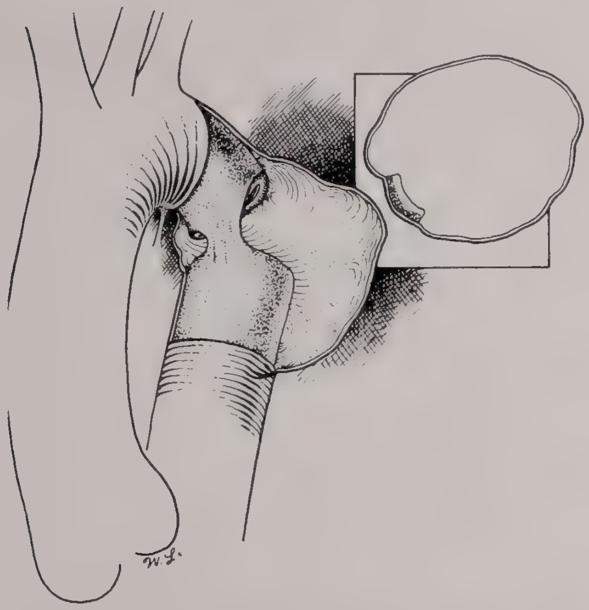


Fig. 3 — Diagram of traumatic aneurysm demonstrating that a portion of aortic wall was intact.

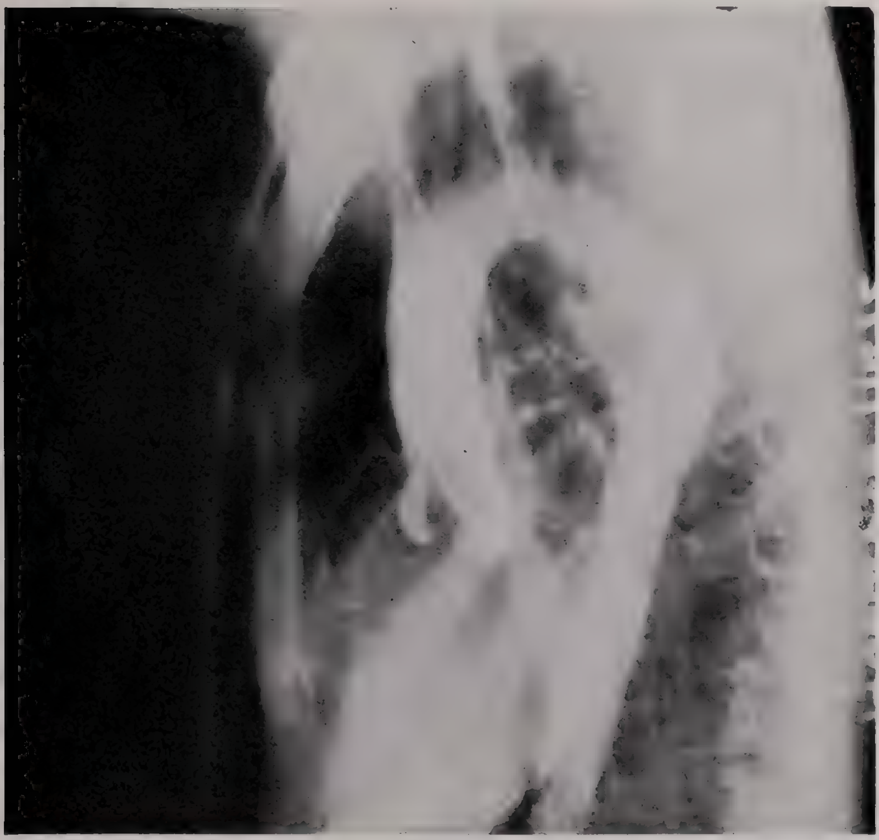

Fig. 4 — Aortogram after aortic aneurysm resection and replacement with Teflon prosthesis.

Continued

symptoms but present with abnormal chest x-ray and the history of injury.[3]

Symptoms when present are related to blood loss, a space-occupying mass, dissection or infection. The blood loss is visible if the aneurysm ruptures into the bronchus or esophagus. The rupture of an aneurysm is usually progressive, and signs and symptoms usually occur prior to total exsanguination. An expanding aneurysm, if contained within the mediastinum, is usually associated with pain. The first bleeding episode generally stops, only to recur again to a greater degree within hours. Dysphagia, dyspnea, cough and hoarseness are symptoms of an aneurysmal mass exerting pressure on the esophagus, bronchus or recurrent nerve. The symptoms of heart failure and sepsis are related to aneurysm dissection and infection and only rarely found.

Diagnosis

A high index of suspicion is most important in diagnosis. Shonholtz[4] et al. emphasized that the orthopedic surgeon sees many of these patients first because of multiple injuries. Every steering-wheel accident or severe chest-wall impact ought to have a careful x-ray evaluation of the mediastinum. Wyman[5] in 1953 called attention to the clues relating to aortic trauma, that include mediastinal widening, aortic arch dislocation, and aortic arch indistinctness. Steinberg[3] has found that fluid in the left chest associated with a localized bulge adjacent to and indistinguishable from the aortic knob is suggestive of aneurysm. Emergency forward venous aortograms can be done readily, even on the seriously ill, by injecting contrast material into the right atrium and taking films based on the circulation time.[6] The more chronic aneurysms can be better visualized by retrograde arterial study.

Treatment

After Blalock[7] first successfully treated a thoracic aneurysm related to penetrating trauma, it was speculated that aneurysms relating to blunt trauma could be similarly managed surgically. Bahnson[8] was the first to resect an aneurysm and repair an aorta. If the aortic repair was such that there was inadequate approximation of normal aortic wall, recurrence was noted. DeBakey and Cooley[9] first resected a traumatic thoracic aneurysm that was recurrent. Hypothermia was used to permit aortic occlusion and a homograft employed to establish aortic continuity. Teflon and dacron prostheses are now thought to be superior to a homograft. Alley[10] has pointed out that there usually is no loss of adjacent normal artery. It is, therefore, sometimes possible to do a direct anastomosis of the proximal and distal aorta without insertion of a graft.

In order to avoid upper body hypertension and poor perfusion to the lower body during aortic occlusion, oxygenated blood has been delivered to the arterial system below the diaphragm by two methods. Gerbode[11] has recommended the use of a shunt from the left atrium to the femoral artery, while a temporary shunt from the left subclavian artery to the distal aorta has been used by Stranahan.[12]

Although in recent years it has been shown that surgical management of traumatic aneurysms can be done with a low mortality,[13] and rupture of aneurysms has been reported to occur as long as eight years after injury,[14] there is a place for nonoperative treatment. Steinberg[3] reports one patient alive with an aneurysm 27 years after injury. In the poor-risk patient, observation is indicated if the aneurysm is stable and asymptomatic.

Historical Background

Vesalius in 1557[15] first recorded a case of traumatic thoracic aneurysm. He made this diagnosis when two physicians presented him with a patient who had a posterior thoracic pulsating mass. There was a history that the man had been thrown from a horse some years earlier. The diagnosis was confirmed at autopsy.

Apparently the next described case of chronic aneurysm after thoracic injury is that of Heller in 1904.[16] A thirty-seven-year-old man fell while carrying a heavy weight that landed on his chest. Eight months later the man died of heart failure. At autopsy, two transverse partial tears of the ascending aorta were found, one of which had dissected and loosened one of the aortic cusps, giving rise to aortic insufficiency.

Shennan[17] in 1929 described a pedestrian who was struck by a bicycle and then developed an aneurysm that ruptured into the esophagus eight weeks later.

In 1948 Stryker[18] noted a traumatic saccular aneurysm with involvement of bacterial endarteritis.

Hollingsworth[19] in 1952 emphasized that post-traumatic aneurysms most frequently arise distal to the subclavian artery, and this diagnosis was entertained if persistent widening of the mediastinum appeared after an automobile accident.

Etiology

In 1947 Strassman[1] found 72 cases of traumatic aortic rupture in a series of 7000 consecutive autopsies at a city general hospital. The most common cause was automobile accident; but it is interesting to note that there were more pedestrians with this injury than passengers. Falls and crushing injuries were other causative factors.

Parmley[2] et al. collected 296 cases of nonpenetrating traumatic aortic injury. They found that 80% expired immediately and approximately 15% died of bleeding after admission to the hospital. About 5% were patients that survived an aortic tear and developed a false aneurysm.

DeBakey[20] has stressed that destruction of the medial layer leads to aneurysm, be it by degenerative disease or trauma. This medial injury may not be readily apparent. Suspecting aortic rupture Eiseman[21] explored a patient with chest-wall injury and found only diffuse subadventitial ecchymoses without bulging of the vessel wall. However, the patient went on to develop aneurysm.

Although blunt trauma to the chest wall seems to be a common denominator for all traumatic thoracic aneurysms, deceleration has been given 'credit' as a causative factor.[22,23] However, carefully documented cases of deceleration injury without chest-wall trauma have not been recorded.

Biomechanics and Experimental Aneurysm Production

In 1918 Oppenheimer[24] studied the bursting pressures of the normal aorta and found that a pressure of over 1000 mg. Hg. would not cause rupture. Lloyd[25] noted a high incidence of cardiac and vascular injuries

Continued

when he studied the effect of closed-chest injury on the bronchus. Stapp[26] in 1957 found that the hog's aorta could be ruptured by having the hog's chest strike a conventional steering wheel.

In 1944 Hass,[23] after studying aircraft accident victims, believed that unequal rates of deceleration of various body parts resulted in great stress at the point of connection.

Cammock[27] believed that when blunt trauma to the chest occurred, the sternum was brought into contact with the vertebral column and the heart was displaced into the left chest, exerting various stresses on the aortic wall. The tear extended from the intima towards the adventitia because maximal stress was at the inner vessel wall. Because the elastic limit of the adventitia was less than that of either the media or the intima, the rupture did not need to be complete.

Moffat, Silbergleit, Robert and Berkas[28] in 1965 have shown that a single blow to the dog's midsternum can cause a transverse aortic tear that will later give rise to aortic aneurysm.

Summary

Aortic aneurysm may be a result of major blunt-chest trauma. The recognition of a progressive aneurysm followed by a planned operative repair can result in the salvage of a person with a single correctable defect.

Hyperventilation

JAMES A. MORIARTY, M.D.*
Minneapolis, Minnesota

Hyperventilation is a common syndrome which generally has a chronic course with recurring acute exacerbations. There is a tendency to simulate grave organic disease. This syndrome is caused by organic or psychogenic factors or a combination of both.

Most often the patient's complaint implicates the cardiovascular system. Next in frequency are the neurological, musculoskeletal, gastrointestinal, and respiratory systems. Psychiatric symptom complexes are less frequently encountered. (See Table 1.)

Lewis reported 50 cases of hyperventilation syndrome. In only one of these many cases was the diagnosis of hyperventilation made prior to admission to the hospital.[1] Peripheral paresthesia was the most consistent symptom. Disorder of breathing was the most common sign. Psychiatric disorders were the only instances in which the apparently correct diagnosis of hyperventilation was made prior to admission to the hospital.

Symptoms and Diagnosis

The diagnosis of hyperventilation is confirmed by inducing an acute exacerbation of the typical syndrome with a few minutes of voluntary overbreathing. The symptoms which develop are followed by marked apprehension and more hyperventilation. The apprehension in addition stimulates neuroendocrine mechanism and thus the cycle is complete and repeats. Tetany may result because of decreased ionization of calcium caused by the alkalinity of the intracellular fluid. In severe respiratory alkalosis convulsions may result.

Hyperventilation often produces unilateral symptoms such as numbness, tingling, weakness, muscle pain, and spasm. These symp-

toms are more apt to occur in the upper extremities but may involve half of the body, and they tend to occur on the side opposite the dominant side, that is, the left side in most cases. Sixteen per cent of 90 volunteers showed pronounced inequality of symptoms beginning unilaterally. About the same percentage showed decreased strength by grip dynamometer, averaging 14 pounds difference.[6]

The Mechanism of Production

Psychic Factors

The psychic pattern of hyperventilation begins with a precipitating process such as some somatic or psychic factor. Carbon dioxide deficit results. The increased output of carbon dioxide is followed by a decreased carbonic acid, a rise in serum pH and a diminution in plasma bicarbonate. The kidneys excrete sodium and potassium as bicarbonate and the carbon dioxide combining power is thus lowered.

Alkalosis

The degree of alkalosis can be maintained for many hours without effects.[2] After 60 minutes of hyperventilation at what appears to be normal depth of respiration, two or three deep breaths precipitated carpopedal spasm. Okel[2] noted no change in serum calcium. However, the inorganic phosphorus decreased and the carbon dioxide combining power decreased from 20.3 mq. per liter to approximately 13 mq. per liter in four volunteers.

Drop in Carbon Dioxide vs. Symptomalogy

In 1942 Davis and Wallace offered the hypothesis that the electroencephalogram slowing during hyperventilation was due to phasic vascular constriction with ischemic anoxia. Gibbs et al., taking exception to Davis' hypothesis, insisted that the electroencephalogram change was due to a decrease in cerebral carbon dioxide tension. This implied that there was a lack of some specific property of carbon dioxide per se on the nerve cells and cell membranes.

The Fall of Arterial Carbon Dioxide Tension vs. the Electroencephalogram

The mechanism of action was thought to be due to cerebral ischemic anoxia resulting from hypocapnic cerebral vascular construction, lack of some specific property of carbon dioxide per se on nerve cells and membranes, or to some effect of cerebral alkalosis.[5]

Effect of Hyperventilation

Using the nitrous oxide technique, Ketty and Schmidt[4] showed that the effect of hyperventilation on cerebral blood flow was a diminution of cerebral blood flow but no change in cerebral oxygen consumption. The blood flow was decreased 35 per cent. Meyer and Goth[5] made the conclusion, based on the concurrent recordings of the electroencephalogram, cortical blood flow, oxygen tension, carbon dioxide tension, and pH from several areas of the brain, that the electroencephalogram slowing in monkeys during hyperventilation was the result of hypocapnic constriction of cerebral vessels resulting in decreased cerebral blood flow and ischemic anoxia and not due to lowering of the brain's carbon dioxide tension. McHenry also noted no change in the cerebral metabolic rate with hyperventilation whether the subject was awake or anesthetized. There was a progressive drop in the venous oxygen content which paralleled to a certain extent the falling cortical tension, but without reaching critical oxygen levels.[3]

Oxygen Tension

Simultaneous evaluations were made of the oxygen tension by oxygen electrode, carbon dioxide tension with a carbon dioxide electrode, pH, sodium and potassium ions with glass electrodes, reflection oximeter for oxygen saturation, electroencephalogram and expired carbon dioxide as measured by infrared gas analyzer. The only measured factor[5] which had any statistical correlation with electroencephalogram flowing in response to hyperventilation was oxygen tension of the internal jugular vein. The thresholds of jugular oxygen tension for electroencephalogram slowing were distributed throughout a narrow range of about 21 mm. of mercury while the jugular pressure of carbon dioxide and jugular pH were scattered widely above and below normal values.

One of the cases studied was a Pickwickian syndrome in which a 16-year-old girl with carbon dioxide narcosis and obesity had extremely high jugular carbon dioxide tension of 75 mm. of mercury. Electroencephalogram slowing occurred at 22 mm. of mercury oxygen pressure in the jugular vein. Goth[5] did not believe that the lack of carbon dioxide was a primary cause of electroencephalogram slowing during hyperventilation. It was further noted that electroencephalogram slowing appeared during hyperventilation with 100% oxygen if the cerebral venous oxygen tension fell below the threshold; it just took longer.

Carbon Dioxide Tension

The cerebral venous flow was proportionately reduced with decreases in the blood carbon dioxide tension. Measured by thermo velocity the decrease was 30 to 40 per cent. The pH change during hyperventilation of +0.085 units decreased the release of oxygen from hemoglobin and resulted in tissue hypoxia. This is known as the Bohr effect. Relative decreases of the jugular oxygen tension were 27.1 per cent Bohr effect and 73 per cent as a result of the decreased cerebral blood flow during hyperventilation.

Below the age of 35 the cerebral vascular constrictive response to hypocapnia is more active than in the older group. The Bohr effect remains the same in both old and young individuals. Thus the electroencephalogram slowing with hyperventilation was more frequent in younger subjects and decreased with advancing age. However, the threshold of cerebral venous oxygen tension at which electroencephalogram slowing appeared was the same regardless of age.

Occlusive Vascular Disease

The presence of occlusive vascular disease did not abolish cerebral vasomotor reactivity, nor did it reduce it more than the age process itself accounted for. A-V malformation resulted in less reduction of cerebral venous oxygen tension because of shunting of the oxygen. Epilepsy caused no variation of the changes. Carbon dioxide narcosis eventually resulted in lowering of the jugular oxygen tension and the electroencephalogram slowing at the threshold oxygen tension.

The anoxic threshold for electroencephalogram slowing in a man with hyperventilation was approximately 21 mm. of mercury in the cerebral venous oxygen measurement. Similar studies without hyperventilation showed that the loss of electroencephalogram pattern occurred at 19 to 20 mm. of mercury, jugular oxygen tension unconsciousness at 16 to 17 mm. of mercury.

Minimal partial pressure of cerebral venous oxygen during hyperventilation showed a maximal reduction of cerebral blood flow in man as compared to controls. The maximal reduction of cerebral blood flow was 60 per cent by hyperventilation. The oxygen saturation fell approximately 30 per cent in man.

Treatment

For treatment of hyperventilation a simple and direct program is effective in 70 per cent of the patients who have demonstrated the symptomatology. An explanation of the physiologic basis for the symptoms is effective. Twenty per cent of the patients[1] achieved partial improvement and only ten per cent were unaided because of what was thought to be depression or hysteria.

When you are an anvil be patient; when a hammer, strike. — Arabian Proverb

The Net-Net Lease

With property taxes and maintenance increasing substantially and constantly in recent years, it has become increasingly difficult to write a long-term lease assuring a property owner an equitable return on his investment. In many cases, taxes and maintenance have doubled — and occasionally tripled over a five-year period. In addition, it is generally necessary to estimate these costs even prior to construction, and these estimates will frequently vary as much as 25 to 50% from actual experience after the project is in operation.

The first trend toward a solution of this problem was an "escalator clause" for rent. Basically, this clause provides for the adjustment of rents upward whenever property taxes exceed a certain amount. This requires frequent adjustment of rent and generally results in one or two years of operation at low profit or a loss due to the time lag between assessment of taxes and adjustment of rents.

As an obvious and simple solution to a problem severe enough to result in the occasional bankruptcy of a landlord, the "net-net lease" has come into popular use in recent years. This type of lease is not a new idea, but its use until recently was pretty much limited to very large ventures such as multimillion dollar buildings in large metropolitan areas.

Basically, the "net-net lease" provides for the payment to the facility owner of a fixed rental based upon a percentage of original investment in land and buildings. In addition, the tenant assumes the liability for all taxes, insurance, utilities and maintenance. Under this arrangement, the owner is not liable for anything except amortization of any debt on the facility.

The landlord's cash position can be readily determined by comparing rental receipts to mortgage payments. His tax position can be determined by reducing rental receipts by the known figures for depreciation and interest.

Rental rates on this type of lease vary with the term of the lease. Generally about 9% of original investment is maximum on a five-year lease, 8½% on a ten-year lease and 8% on a fifteen to twenty-year lease.

To illustrate the simplicity of such a lease, assume the owner invests $30,000 in land and an additional $90,000 in building for a total of $120,000. He leases it on a ten-year basis at 8½% "net-net." The tenant pays *all* expenses including utilities, repairs, taxes, insurance and janitorial service; and in addition, pays the owner $10,200 annually. The lease provides the same default provisions for failure to pay all expenses as standard leases provide for nonpayment of rent.

Assume further that the owner has a twenty-year mortgage for $80,000 at 5½%. His *cash* position is $10,200 rental receipts less $6,605 mortgage payments. *Taxwise*, his $10,200 rentals are offset by average annual interest of $3,600 and maximum tax depreciation averaging $3,000. His average taxable income during the first ten years will be about $3,600 or 3%. His true economic yield will be $10,200 less estimated depreciation of 2%, or $1,600, based upon projected economic market value at the end of ten years, or $8,600 (7.2%).

While this approach is very logical for large single-tenant properties such as drug stores, grocery stores, filling stations and other commercial properties, it is generally not too well suited for multiple-tenant projects due to the problems of apportioning taxes, insurance and other expenses. It can, however, have application where, for example, one member of a partnership owns a building which he rents exclusively to the medical partnership.

Such leases can also be used in conjunction with about all "option-to-purchase" arrangements.

If you now own or are considering purchase of a rental facility, this rental technique may be "tailor-made" to assure you a constant equitable return on your investment.

Big Mountain Medical-Ski Conference — 1966

Hope you will plan now to join us January 26, 27 and 28, at the Big Mountain, Whitefish, Montana. The scientific program will again be restricted to the evenings (7-10 P.M.), so that you may enjoy the whole day skiing. Special entertainment will be arranged for the wives — during each evening's program. Reservations for lodgings should be made direct with: The Big Mountain, Whitefish, Montana. AAGP credit.

Northwestern Component M.A.G.P., Box 220, Columbia Falls, Montana

So live that after the minister has ended his remarks, those present will not think they have attended the wrong funeral. — The Mortarboard

Abstracts, Briefs and Commentaries

CERVICAL SPINE INJURY

Abel has stated that routine views of the cervical spine are of little help in the proper evaluation of patients with relatively minor injuries — whiplash and other mild afflictions of the cervical spine. He did some experimental work on cadavers after dissecting away the neck muscles and placing the necks in a position comparable to a rear-end "whiplash" impact; from these experiments he was able to demonstrate that after the age of one year the deformities in the cervical spine are astonishingly frequent, and that they increase progressively with age. From these findings he concludes that such deformities are acquired and not congenital, as they occur in approximately eight per cent of those under the age of 21.

It has also been observed that the hypertrophic changes in the bodies of the vertebrae occur independently of hypertrophic changes in the apophyseal joint and vice versa.

It is suggested that the hypertrophic changes in the bodies of the cervical vertebrae are largely a response to static weight-bearing stresses, whereas apophyseal joint arthritis is a response to dynamic stresses resulting from the alterations in the planes of motion.

Changes and alterations in any part of the suspension system, which includes the vertebral bodies, the intervertebral discs, and the lateral joints of Luschka and the apophyseal joint, are of the same suspension system, so that the alterations in one of these must eventually be communicated to the others.

Abel indicates that the symptomatology of neck strain is quite variable, both immediately after the injury and some years later. He stresses the value of specialized views of the lateral masses in order to demonstrate the characteristic deformity.

It has been stated by Severy Mathewson and Echtol that the load to the head may exceed 100 pounds for rear-end collisions not exceeding 15 miles per hour, and a peak load of 150 pounds has been recorded in collisions at 10 and 20 miles per hour.

The most frequently observed cervical fractures in these experimental studies by Abel were observed in the interarticular isthmus and lamina of one or more of the lower cervical vertebrae, fractures of the lower process of C1 and/or C2, and fractures of the elements of the joints of

Continued

Luschka. These three types of fractures were not visualized in routine views of the cervical spine.

The cervical spines of twenty-eight cadavers of elderly males and females were anatomically compared with the cervical spines of thirteen females under twenty.

On a statistical basis the authors hypothecated that there was an increased asymmetry of the lateral cervical articular masses with an increase in the age of an individual. He suggested that this chronic remodeling process may be accelerated by post-traumatic changes in the tissues of the surrounding joint capsule or by repeated and prolonged stresses associated with exertion or posture.

Abel found no consistent relationship between the narrowing of the disc space and the apophyseal arthritis at the same vertebral level, because other disc spaces were narrowed without associated arthritis. No consistent relationship was found to exist between disc-space narrowing and asymmetry of the articular masses of the C 4-6 segments.

He concluded that the asymmetry is due to a continuing remodeling in the response to dynamic effect of trauma and the stresses of weight bearing and exertion, causing it to become progressively more accentuated with time.

NOTE: One might question some of Abel's clinical hypotheses, e.g., that whiplash neck strain without appreciable immediate symptoms can be a factor in delayed symptoms in the neck years later. He has, however, made a good case for fractures of the cervical bodies which were ordinarily not visualized in the routine x-ray; and certainly if an acute fracture can be found following injury, one must then accept the cause and effect relationship. If one refers to the dynamic action of physical wear and tear as a common etiologic factor in the development of the changes in the cervical vertebrae, then it would seem more logical that these changes, as observed by Abel with greater frequency through advancing age, could account for the eventual neck pain after relatively minor injury. To account for these changes on the basis of one specific incident would seem to be less likely.

In using the term "dynamic effect of trauma" Schoening probably did not intend to indicate a specific incident of injury. He appears to have proven that the asymmetry of the cervical articular masses is a progressive change observed with advancing age.

One is then left with a dilemma, and it seems most logical to conclude that hypertrophic changes in the cervical spine do appear more often with advancing age and can be a cause of neck pain with or without injury; and also that an incident of strain could be superimposed upon such hypertrophic changes, so that the finding of a recent fracture in the pillar views of the cervical spine following injury must be attributed to the incident.

HYPERTROPHIC GASTRITIS

Giant hypertrophic gastritis was first described in 1888 by Menetrier; since then more than 100 cases have been recorded. Great interest was aroused in later years, owing to excessive loss of albumin through the gastric mucosa, as instances of idiopathic hypoalbumin anemia were found to be due to this disorder. It is important to determine the site of albumin leakage; likewise it is important to determine if the disease in the stomach is due to tumor or inflammation. The writers describe a case of giant hypertrophic gastritis with excessive albumin leakage.

Case Report:

A male, 64 years of age, with achylia and periodic edema of the legs for 20 years is the basis of this report. He developed acute abdominal pain, return of marked edema, voluminous vomiting of mucus, and fatigue. The serum concentration of protein and albumin was extremely low. Intravenous R.I.H.S.A. showed the half life of albumin to be very short; x-ray of the stomach revealed exaggerated mucosa and signs of malignancy. Surgical removal of some of the suspected area disclosed only inflammation.

The patient was treated conservatively for two months with diet and diuretics with little improvement. A Bilroth I gastric resection was performed, the proximal incision being through changed tissue. The patient then improved promptly with normalized serum proteins and increased half-life albumin. Roentgen examination revealed great improvement in the remaining stomach.

The authors have gone into great detail regarding the chemistry, histology, and symptom improvement. Graphs and photographs are excellent. All of these are available for the internist or surgeon who wishes to obtain more complete information.

Discussion: The rarity of this disease is established. The review represents a great deal of effort for which the authors should be complimented.

OVARIES AND CORONARY DISEASE

To test the hypothesis that functioning ovaries are responsible for the relative degree of female protection against coronary heart disease, 2 groups of women, one with bilateral oophorectomy, the other with hysterectomy, were examined. All had been operated upon between 10 and 25 years before and had been under the age of 45 years at the time of the operation. Detailed comparisons of the 2 groups of examined women (267 oophorectomized and 385 hysterectomized) indicated that they were strikingly similar in most respects. The prevalence rate for coronary heart disease was 8% for both groups. These findings suggest that some factor or factors apart from ovarian function is responsible for the relative freedom from coronary heart disease among women as compared with men.

THE TREATMENT OF INOPERABLE CANCER WITH RADIOISOTOPES

The management of inoperable carcinoma always presents a problem. Ariel has described a technique of administering isotopes intra-arterially, either through the femoral arteries for generalized abdominal lesions or through other vascular systems for more accurate localization.

The author makes no exaggerated claims for its value; but he states that it has been well tolerated and he believes that some patients have enjoyed increased longevity and others, some palliation.

Yttrium 90 was the radioactive element used in his series, having a half life of 61 hours.

AMYOTROPHIC LATERAL SCLEROSIS

Study of the onset and course in 70 fatal cases of amyotrophic lateral sclerosis demonstrated that the onset was either atrophic or spastic, in either the bulbar or the spinal area. Regardless of the type and area of involvement, spastic forms nearly always become also atrophic and atrophic-spastic, while spinal involvement spreads to bulbar, and bulbar to spinal areas, if the patient lives long enough. A few cases of purely atrophic disease were found and still fewer of purely spastic disease. These forms represent thus a single degenerative disease, a spectrum having the atrophic process (progressive muscular atrophy) at one end, the spastic (primary lateral sclerosis) at the other, and a combination (amyotrophic lateral sclerosis) in the middle. With time, cases at each end of the spectrum move toward the center. On the average, with considerable spread, the patients reported died 36 months after the onset of spinal spastic sclerosis, 33 months after the onset of spinal atrophic, 24.6 months after the onset of bulbar spastic, and only 17 months after the onset of bulbar atrophic involvement. Since death practically always results from bulbar involvement, life may last almost indefinitely, so long as purely spinal changes exist in this disease.

THE SUDDEN MURDERER

Clinical observation of 43 "sudden murderers" indicated that most of them suffered from a constant conflict between inner feelings of inadequacy and isolation, and conscious needs to succeed and conform. Especially when these persons were at the threshold of a meaningful life adjustment, this conflict created an increasing sense of self-doubt, tension, and repressed rage, culminating in explosive violence. The importance of sustained professional contacts with such patients, even during periods of apparent conformity and adequacy, is stressed.

PATIENTS WITH THREE OBSTETRIC COMPLICATIONS

The purpose of this investigation was to determine the relation between three obstetric complications and certain psychiatric symptoms and personality characteristics as measured by the Minnesota Multiphasic Personality Inventory. One hundred sixty-nine white, unmarried primigravidas living at a home for unwed mothers were given the Minnesota Multiphasic Personality Inventory at the beginning of the third trimester. Three obstetric complications were studied: Premature rupture of the membranes, excessive weight gain, and pre-eclampsia. On the basis of the Minnesota Multiphasic Personality Inventory given again before delivery, patients who experienced any of these three complications were more withdrawn, anxious, and concerned with their bodily functions than those who did not develop them. The patients with premature rupture of the membranes exhibited the least pathology; however, they were more withdrawn than the control group. The patients with excessive weight gain were more anxious, distrustful, passive, dependent, and aware of their bodily functions than the control group. The group with pre-eclampsia, like the excessive-weight-gain group, showed greater concern for bodily functions and, in addition, seemed to use physical symptoms as a means of solving personal difficulties. The excessive-weight-gain and pre-eclamptic groups thus overlapped in some personality characteristics and were generally more disturbed than those patients who experienced premature rupture of the membranes. This investigation supported previous findings that women who develop pre-eclampsia or who become excessively overweight early in pregnancy frequently exhibit psychopathology.

LYMPHATIC DRAINAGE OF THE BREAST

Studies done by Halsell et al., in which they injected sky-blue dye directly into the intradermal tissue about the nipple areola, reveal that the dye enters the lymphatic through a few selective trunks from the primary injection site and thereafter courses toward the axilla. From this superficial position the lymphatic progresses to deeper tissue, suggesting that the more peripherally situated portion of the skin flap is farther away from the lymphatic channels than that of the areola.

It might have proven additionally valuable to have made the initial injection of the dye in the depth of the breast substance adjacent to the tumor, simulating thereby more nearly the lymphatic drainage from a malignant lesion lying within the breast substance rather than in the interdermal tissue of the areola.

LUMBAR SYMPATHECTOMY

The results of 198 lumbar sympathectomies, performed upon 133 patients (average age 60 years) with various peripheral vascular diseases, are evaluated. The diseases included arteriosclerosis obliterans, diabetic gangrene, embolism-thrombosis, thrombophlebitis, frostbite, and causalgia. In 90 patients arteriography was performed at the time of sympathectomy, which has been discontinued as a routine procedure since 2 of the deaths in the series were directly attributable to the arteriography. Correlation of good results with arteriography was possible in 73% of cases. Amelioration or relief of symptoms occurred in 79% of cases. The morbidity rate was 2%, and mortality was 3.5% (increased by arteriography). Amputations were required in 30%. The authors feel that lumbar sympathectomy remains a valuable procedure in selected cases of peripheral vascular diseases, particularly those which are primarily vasospastic in nature or in which the arterial obstructive process is not too advanced and extensive. The routine use of common iliac arteriography is not recommended, but it should be judiciously applied in selected cases.

HOMONYMOUS HEMIANOPIA

The role of the quantitative study of visual fields in the diagnosis of topical neurologic disorders was studied in 100 patients with homonymous hemianopia, who were examined by tangent screen techniques and a projection perimeter. One-fourth of the hemianopias were produced by temporal lobe lesions, usually occurring in the younger age group and equally distributed between the 2 sexes. The most frequent etiologic factor was a neoplasm. Except when there was also parietal lobe extension, the optokinetic response was normal. In one-third of this series the hemianopia had originated in parietal lesions, which occurred in an older age group and apparently more frequently in men than in women. The optokinetic nystagmus, present in 28 cases in this series, was of great diagnostic value, for not a single patient with parietal lobe hemianopia showed normal optokinetic response. Occipital lobe lesions, the most common casue of hemianopia, was the etiological factor in two-fifths of the patients studied, occurred mainly in the older age group (50 years was the average age) and was found more frequently in men than in women. In contrast with temporal lobe lesions, the occipital lobe defects originated in vascular lesions rather than in tumors, in a 3/1 ratio. The optokinetic sign, usually negative, was positive in 7 patients. Two arteriovenous malformations were detected, in each case associated with a mass lesion. Visual acuity was within normal limits in the entire series, indicating that a patient can see 20/20 with one half of the macula.

Character development is the great, if not the sole, aim of education. — O'Shea

SURGERY OF THE BILIARY PASSAGES AND PANCREAS — **Dr. Walter Hess, Van Nostrand Company, Princeton, New Jersey.**

This is a very thorough book of 624 pages containing opinions and advice of the author based on a large personal series, and his own evaluation of literature on this subject.

The author is clinical professor of surgery at the University of Basle, Switzerland. He was formerly professor of surgery at the Medical School of the University of Alexandria, Egypt.

The book contains good anatomic operative drawings of technique and pathology. Reproductions of x-rays have line drawings adjacent as an excellent method of explanation.

The section on postoperative complications presents many of the problems of biliary and pancreatic surgery, and suggestions for their management. The author emphasizes his own concept of a complete intraoperative diagnosis, and as part of this concept has a large section on radiomanometry after the method of Caroli. This is described as a careful and detailed method of investigation of the biliary duct system at the time of surgery. The reviewer recommends a careful study of this section.

Surgery relative to the sphincter of Oddi and the problems of chronic pancreatitis seem to omit some of the methods currently popular in American surgery, but is otherwise quite complete.

The book makes an excellent text for this subject, covering sufficient background material of anatomy, physiology, pathology, and has an adequate index and quite extensive coverage.

CONGENITAL HEART DISEASE — **Correlation of Pathologic Anatomy and Angiocardiography, Edwards, J. E., Carey, L. S., Neufeld, H. N. and Lester, R. G.; W. B. Saunders Co., Philadelphia, 1965; 890 pages, 2 volumes, price $45.**

Congenital heart disease in this two-volume work is subtitled Correlation of Pathologic Anatomy and Angiocardiography; however, the correlation includes far more than pathology and roentgenology, considering all the major clinical aspects of congenital heart disease. This is an unusual if not a unique work. The authors have started with a simplified outline of congenital heart disease, covering the subject under five headings: increased pulmonary arterial vasculature with cyanosis present; increased pulmonary arterial vasculature with cyanosis absent; decreased pulmonary arterial vasculature with cyanosis present; normal pulmonary arterial vasculature with cyanosis absent; and pulmonary venous obstruction. This is mainly a clinical outline, and pathologic entities appear in several sections, as, for instance, the same disease with or without cyanosis. The outline is closely followed, starting with typical illustrations of various entities and ramifying into a thorough study of associated defects. The typical treatment of each entity includes a detailed anatomical description with minimal text and maximal use of illustration in black and white, followed by a brief description of the clinical features and altered physiology. The radiographic and angiographic material is then presented in profuse illustrative detail, followed by correlation of roentgenographic and post-mortem anatomy.

The text throughout is pared to the lean heart of the matter. Bibliography is sparse and intermingled throughout the text.

The work emphasizes the essential role of roentgenology in the clinical evaluation of congenital cardiac problems (equally true in many acquired cardiac problems as well). The clinician would like to see a fuller treatment of other clinical features, especially electrocardiography and catheterization data.

Doctor Edwards et al. have obviously drawn upon an enormous wealth of material to illustrate in such detail the panorama of congenital heart disease. Withal, they have considered the reader's limitations and divided this massive work into two three-and-a-half-pound, fairly slim although outsized volumes, convenient to hold and suitable for large illustrations. The table of contents is deceptively simple with five items; the index is repeated in both volumes. These books are required reading for a large segment of the medical population: cardiologists, pathologists, and roentgenologists.

The Tobacco Tyrant*

Harf's Practical Therapeutics say: "Tobacco when smoked or chewed to any extent by young persons, stunts the growth of all parts of the body, and is very apt to cause in all users granular sore throat, pharyngitis, laryngitis and faucitis. Sometimes angina pectoris develops. "Tobacco Heart" is a term applied to a condition of this viscus characterized by disorders in its rhythm or power, palpitation, arrhythemia and dyspnea."

Shoemaker says: "Tobacco increases the excitability of the heart by a direct action upon its intrinsic ganglia. The spinal and cerebral centers become affected, and inco-ordination, a staggering gait and vertigo are prominant symptoms of the toxic action. Finally, collapse and death may occur from paralysis of the heart or of the respiration. Similar results also follow the inhalation of tobacco smoke, though generally they appear in a much milder form than when the drug is swallowed. Poisoning has followed the application of tobacco leaves to wounds."

Brunton says: that a sustained low blood pressure in the absence of tuberculosis, usually means excessive smoking.

E. O. Giere, M.D.**
Minneapolis, Minnesota

**Editor's Note: In 1928 Dr. E. O. Giere prepared and presented a manuscript at one of the Twin City hospitals on the evil effects of tobacco.*

***Through the courtesy of his sons, Doctors Richard and Joe Giere, the timeworn and faded manuscript was made available to the editor. Excerpts will be printed serially.*

Virtues of Human Parts

From Pliny we learn that various parts and products of the human body are credited with remarkable virtues. A few instances of remedies drawn from the human body are ear-wax or a powdered tooth against stings of scorpions and bites of snakes, a man's hair for the bite of a dog, the first hairs from a boy's head for gout. Simply tying two fingers or toes together is recommended for tumors in the groin, catarrh, and sore eyes. Or the eyes may be touched thrice with water in which the feet have been washed. Scrofula and throat diseases may be cured by the touch of the hand of one who has died an early death, although some authorities do not insist upon the circumstance of early death but direct that the corpse be of the same sex as the patient and that the diseased spot be touched with the back of the left dead hand.*

An Outline of Basic Enzymology in Blood Clotting[*]

WALTER H. SEEGERS, Ph.D.
Detroit, Michigan

LIKE OTHER mechanisms in physiology the clotting of blood is of tremendous interest to the physician as well as to the basic scientist. In blood banking, surgery, pumping of blood, thrombosis, hemorrhagic diseases, nutrition, wound healing, and practically every phase of medical practice the phenomenon of blood clotting has to be dealt with expertly. This is therefore of such substantial consequence that education in this field is properly promoted with the greatest possible thoroughness and efficiency. During the past quarter century progress in the biochemistry of the blood-clotting mechanisms has been surpassed by no other developments when considered in the light of the unique insights gained, the complexity of the chemistry that has been elucidated, and the formidable difficulties that have been overcome. New examples of nature's ways have been discovered by the application of laboratory technology. The phenomenon of blood clotting need no longer be looked upon as a riddle but can be seen as one of the beautifully integrated systems in our physiology.

Descriptive Observations

Conditions that Retard Clotting

Removal of calcium ions is the most common and effective way to prevent clotting. This can be done by using a chelating agent[**] such as sodium citrate or ethylenediaminetetracetate. Oxalates form microcrystalline precipitates with calcium, while heparin leaves the calcium alone and blocks protein interactions. In like manner hirudin, obtained from the saliva of the leech, is an anticoagulant. Cooling blood, or centrifuging to remove the formed elements and especially the platelets, leaves the mechanisms of the plasma in a balanced state. Lack of vitamin K in the diet, or its faulty absorption due to bile-salt deficiency, is followed by a lowering of

Fig. 1 — Prothrombin is a multipotential protein capable of breaking into subunits. These subunits are themselves active in the generation of thrombin activity. Thrombin and autoprothrombin C are each separate enzymes derived from prothrombin as end products, while autoprothrombin I, II, III, and autoprothrombin II-A are intermediate derivatives. Urea-treated thrombin, trypsin thrombin, and acetylated thrombin are modifications of the thrombin molecule. Acetylated thrombin does not clot fibrinogen but is an esterase.

Fig. 2 — Diagram intended to emphasize that the potential environment needed for prothrombin activation resides in the plasma, platelets, and tissues. Prothrombin is in the plasma together with calcium ions, Ac-globulin (factor V), platelet cofactor I (factor VIII), and fibrinogen. The amount of autoprothrombin I (factor VII?) and autoprothrombin II (factor IX), which is in plasma, if any, is unknown on a quantitative basis. Both are derived from prothrombin when blood clots. The platelet materials are made available when the platelets undergo morphological change due to contact with surfaces, and/or thrombin. Tissue materials function following injuries that break the cellular structure.

plasma prothrombin concentration and reduced clotting power. Reduced liver function due to tissue pathology or inhibition of the metabolic machinery, as with dicumarol and related compounds, may be associated with restricted supplies of prothrombin in the blood plasma, and slow clotting of the blood. Lytic agents that are capable of destroying fibrinogen can eliminate the very possibility of fibrin formation. The surface characteristics of the vessel in which the blood circulates or into which it is received may either promote or retard clotting, depending upon the electric charge, hydrophobic and hydrophilic properties, and wettability. Paraffin-lined or silicone-treated glassware is perhaps the most commonly used surface for maintaining the normal fluidity of the blood.

Accelerated Clotting

Surface contact with many substances and especially gauze packs and tampons accelerate clotting. Gently agitating the blood or elevating the temperatures hastens clotting. Rapid clotting follows upon the addition of thrombin, tissue extracts, certain snake venoms, the enzyme autoprothrombin C, and several other enzymes.

Origin of Thrombin

With strong thrombin solutions it is possible to clot blood in less than one second. Normally plasma contains 300 times more thrombin than is needed for clotting in 15 seconds, but it is there in an inactive form. How does this dormant procoagulant power unfold itself when needed, and how does it do so at undesirable times, as for instance in thrombosis? This profound question in biology has been the topic of intense research since Alexander Schmidt first discovered prothrombin in the past century. From work with purified prothrombin and other purified components of plasma, several of the basic reactions are known. There may be a certain sequence in which these occur, but in general many reactions run their course at the same time. Despite these complexities, however, it is now possible to formulate an interpretation of the mechanisms of prothrombin activation in terms of enzymology. The key to the modern enzyme concept of blood clotting was the very nature of the prothrombin molecule itself. It was found to be a molecular system for which there was no prior model in the literature of biochemistry. In the prothrombin molecule itself reside the subunits that are needed for rapid thrombin generation (Figure 1). Prothrombin activates itself and needs only the proper environment for unfolding its clotting power.

Environment for Thrombin Generation

A most ingenious arrangement in our physiology consists of using three separate compartments for the distribution of the ingredients for creating the prothrombin activation environment. The three locations are the platelets, plasma, and somatic cells. The ingredients of platelets + plasma (intrinsic system) make an adequate combination of substances for thrombin generation, but clotting occurs only slowly. Platelets + plasma + cellular elements (extrinsic system) may give a combination or environment for rapid clotting. A break through the blood vessel wall thus provides the ultimate mobilization of procoagulant power because it calls upon the platelets, tissues, and plasma resources all at one time to furnish the environment which prothrombin needs for its activation (Figure 2). I shall then consider the recently developed perspective under three main divisions as follows: (1) characteristics of the prothrombin molecule, (2) subunits of the prothrombin molecule, and (3) conditions for the spontaneous activation of prothrombin.

Characteristics of the Prothrombin Molecule

The prothrombin molecule isolated from bovine plasma has a molecular weight of 69,000. With the electronmicroscope the particles are seen to be uniform when one molecule is compared to another (Figure 3). Many years ago I found that purified prothrombin would spontaneously convert to thrombin in certain strong salt solutions such as sodium citrate. Some years later, the experiment was repeated, and it was found that autoprothrombin C (thrombokinase) activity developed at the same time and at the same rate as thrombin. Thus it was discovered that

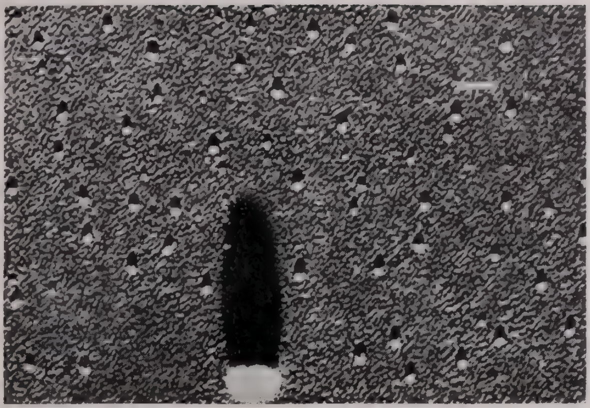

Fig. 3 — Shadow-cast electronmicrograph of bovine prothrombin produced by Jeanne M. Riddle. The white bar is a thousand angstrom units in length. The polystyrene latex standard has a diameter of 1380 microns.

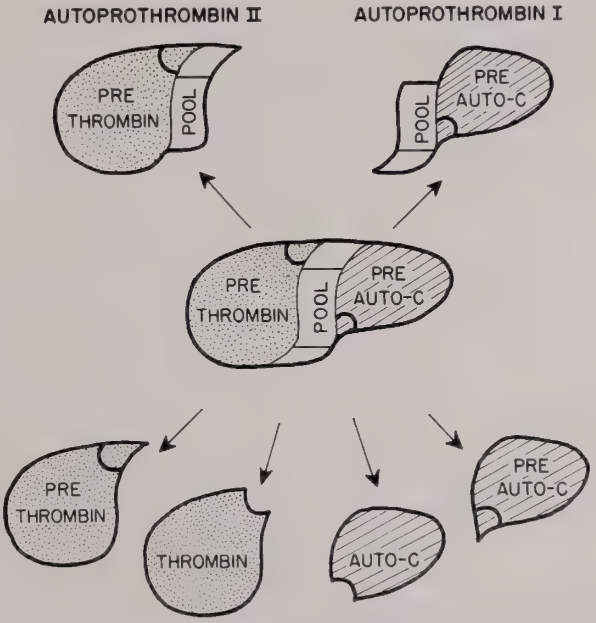

Fig. 4 — The prothrombin molecule contains the enzymes thrombin and autoprothrombin C, and in addition a "general" pool of protein material as well as carbohydrate. The molecule can be split in several different ways with the use of thrombin and autoprothrombin C. The diagram is supposed to suggest the nature of the substances isolated up to now. Note that the protein pool may associate with the prethrombin portion of the molecule or with the preautoprothrombin C.

the prothrombin molecule contains two enzymes, and that nothing besides prothrombin is actually needed to obtain these two enzymes. In one experimental stroke it was shown that all else concerned with prothrombin activation has to do with environmental conditions. Furthermore, it was found that other subunits of the molecule that can be produced are important in prothrombin activation (Figure 1). How are these subunits split from the original prothrombin, and what is their function in the generation of thrombin activity?

Fig. 5 — Prothrombin activation can begin upon surface contact, whereupon there may be plasma changes as well as platelet dissolution. Thrombin reaction specificity is governed by Ac-globulin. The autoprothrombin C in the prothrombin remains mostly, if not entirely, in the precursor form called autoprothrombin III. Thrombin produces a lipid inhibitor from inhibitor source material that is neutralized by platelet cofactor I (factor VIII). This route of prothrombin activation is self-limiting.

Fig. 6 — The platelet-plasma activation of prothrombin involves autoprothrombin II which can be derived from prothrombin due to thrombin Autoprothrombin II (platelet cofactor II, PTC, factor IX, Christmas factor, hemophilia B factor) is in a sense a substitute for platelet cofactor I (factor VIII), but is not neutralized by the lipid from inhibitor source material.

Subunits of Prothrombin

As a crude device for purposes of education I have created an imaginative geometrical projection of the prothrombin molecule and some of its major subunits (Figure 4). To see how these are created and function in our physiology, six important questions can be asked, each one of which has been answered on the basis of experimental inquiry. What happens to prothrombin when added to the following:

Thrombin .... = ?
Thrombin + Ac-globulin (factor V) ...... = ?
Thrombin + Ac-globulin + lipid .... = ?
Autoprothrombin C .... = ?
Autoprothrombin C + Ac-globulin ...... = ?
Autoprothrombin C + Ac-globulin + lipids = ?

In the presence of the enzyme thrombin (M.W. = 33,700) the prothrombin substrate changes to autoprothrombin II (factor IX). This subunit, with a molecular weight 41,500, is not an enzyme but contains thrombin within its structure (question 1 is answered). Prothrombin also activates in the presence of autoprothrombin C (M.W. = 24,000 ?), but unlike the activation product with thrombin, another subunit called autoprothrombin I_c (M.W. = 34,000) is obtained. This is not an enzyme, but contains autoprothrombin C within its structure (question 4 is answered). By adding Ac-globulin (M.W. near 99,000 ?) a protein normally in plasma, the reaction specificity of the enzyme thrombin as well as the reaction specificity of the enzyme autoprothrombin C is changed, and the subunits of prothrombin which are produced are autoprothrombin III (preautoprothrombin C) and thrombin (questions 2 and 5 are answered).

Thrombin and autoprothrombin C by themselves specifically produce distinct activation products. In the presence of Ac-globulin the activation products are the same for each enzyme. *The function of Ac-globulin is to govern the reaction specificity of two enzymes: namely, thrombin and autoprothrombin C.* Ac-globulin is thus a coautocatalyst or a special coenzyme. Lipids, such as cephalin, by means of hydrophobic and hydrophylic molecular attraction and repulsion plus surface activity supply an environment for prothrombin to activate rapidly and do not change the end product (questions 3 and 6 are answered).

Physiological Integration for Spontaneous Activation of Prothrombin

Initiation of Prothrombin Activation

Prothrombin itself contains all that is required to have thrombin. It activates itself whenever it is in a suitable environment. Most likely minute amounts of thrombin generate at all times in our circulation and are disposed of by antithrombin. So one ought to speak of accelerated prothrombin activation rather than the initiation of such an event. In any case, tissue extracts are prominent procoagulants that can produce rapid acceleration. Platelets can disintegrate upon contact with glass, tissues, collagen, and other surfaces. Some evidence indicates that a special protein (factor XII) activates upon contact and supplies procoagulant power; however, patients with such a deficiency are not prone to bleeding. The main impetus for thrombin generation comes from platelets and tissues, while the prothrombin molecule itself is sensitive to surfaces including the lipids contained in platelets and the lipoproteins of tissues.

Plasma-platelet Activation Sequence

Upon suitable surface contact protein(s) alterations can occur and the platelets break up to supply platelet factor 3. This is sufficient, with the plasma components Ac-globulin + calcium ions + platelet cofactor I (factor VIII, antihemophilic factor), to accelerate thrombin generation. This thrombin uses prothrombin as a substrate and the reaction specificity is governed by Ac-globulin. This is an autocatalytic feedback system (Figure 5). The precursor of autoprothrombin C found in the prothrombin molecule (autoprothrombin III) does not activate, or if it does, then only a very small percentage of the total potential becomes active.

The chemical events accelerated by surface contact and the platelets would be a threat to life if started within the blood vessels. A counterforce is generated by thrombin through the utilization of inhibitor source material of the plasma. The inhibitor neutralizes platelet cofactor I (factor VIII) activity, and for that reason platelet cofactor I is inactive in serum. The inactivation of platelet cofactor I would soon be noticed as retarded thrombin generation, because antithrombin would neutralize thrombin, and there would be no more thrombin remaining or any new thrombin generated. As a consequence prothrombin activation has to be continued in a newly created environment. This is possible by means of another regulatory function of thrombin.

By means of thrombin a new platelet cofactor activity develops while the above

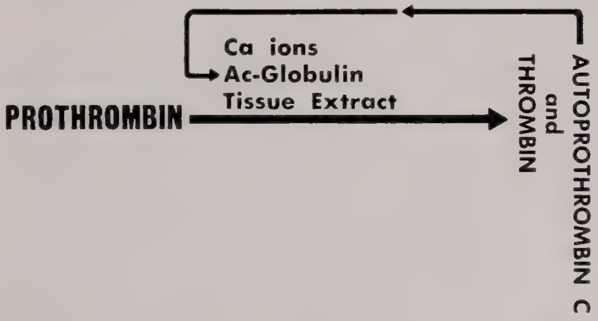

Fig. 7 — With the introduction of tissue extracts, active autoprothrombin C is produced as well as thrombin. Both enzymes then participate in the generation of thrombin activity. Ac-globulin is not essential for the generation of autoprothrombin C activity.

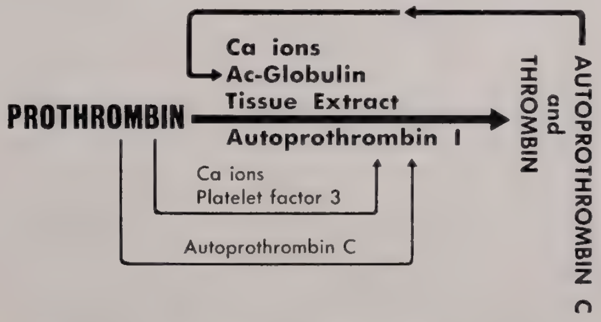

Fig. 8 — The effect of tissue extracts in the generation of thrombin activity is potentiated by the formation of autoprothrombin I. This activity develops in the presence of platelet factor 3 and also in the presence of autoprothrombin C.

described events are occurring (Figure 6). This is autoprothrombin II (factor IX or platelet cofactor II). Thrombin can form this derivative from prothrombin because the Ac-globulin does not completely enforce the reaction specificity which makes thrombin break prothrombin bonds at the site which gives thrombin. Some of the thrombin attacks at the site which is the primary target when Ac-globulin is not there at all. With cleavage of the prothrombin molecule at this point autoprothrombin II forms. In this laboratory autoprothrombin II was formerly called platelet cofactor II because it is really a substitute for platelet cofactor I. Notice that, except for the term autoprothrombin II or platelet cofactor I, the heavy lettering around the two arrows of Figure 6 is identical. This can be illustrated for explicit comparison as follows:

Ca ions	Ca ions
Platelet factor 3	Platelet factor 3
Ac-globulin (factor V)	Ac-globulin (factor V)
Platelet cofactor I (factor VIII)	Platelet cofactor II (factor IX)
Thrombin	Thrombin

For certain functions, platelet cofactor I (factor VIII) and platelet cofactor II (autoprothrombin II, factor IX) are interchangeable. The usefulness of each one depends upon the time sequence, and upon the exclusive capacity of platelet cofactor I to accept an inhibitor. Platelet cofactor II is found in serum and is not inactivated by the inhibitor for which platelet cofactor I is the receptor.

The chief reason for the slow clotting of the platelet-plasma system resides in the fact that autoprothrombin C remains in its precursor form: namely, autoprothrombin III. If any active autoprothrombin C forms, the quantity is small. Thrombin may be the only enzyme for prothrombin activation under the conditions where platelets + plasma are involved. It is not a very effective procoagulant when the coenzyme concentration (Ac-globulin) is no higher than found in plasma.

Tissue-platelet-plasma Activation Sequence

With Ac-globulin in plasma, thrombin generation can be accelerated with tissue extracts alone. Autoprothrombin C activity develops in large quantities due to the materials of tissue extracts (Figure 7). These materials are primarily lipoproteins and cathepsin. Ac-globulin is not necessary for the development of autoprothrombin C activity. The autoprothrombin C has its reaction specificity governed by Ac-globulin so that it tends mainly to convert prothrombin to thrombin. As stated previously, the same is true for thrombin. The two enzymes thus work synergistically. In test tubes the tissue-extract concentration and the Ac-globulin concentration can be set so high that the activation of prothrombin is rapid and almost exclusively to thrombin and autoprothrombin C (Figure 7), without the formation of any other prothrombin subunits.

In natural clotting, tissue extract and Ac-globulin are in limited concentration and clotting would be slow except that there is another mechanism for accelerating thrombin generation. This consists of producing autoprothrombin I. It occurs in two ways (Figure 8). In one way the reaction specificity of autoprothrombin C is not completely enforced and some of the autoprothrombin C converts prothrombin to autoprothrombin I_c (factor VII ?). The latter functions as an accelerator. Another pathway for autoprothrombin I generation develops, due to platelet factor 3. This lipoprotein called platelet factor 3 tends to induce the conversion of prothrombin to autoprothrombin I_p (factor VII ?), and this derivative is also an accelerator. Autoprothrombin I_c and autoprothrombin I_p can hardly be distinguished from each other on the basis of kinetic experiments. They are, however, easily seen to be different substances on the basis of solubility and stability characteristics. Neither is *necessary* for the development of autoprothrombin C activity or for the generation of thrombin activity. They are accelerators.

The full procoagulant power of blood and tissues is brought into force by the operation of several reactions (Figure 9). With its limitations Figure 9 can serve to reduce to a conceptual basis volumes of information gathered since the time of Alexander Schmidt. This way of viewing one of the most important reactions in biology is really an interpretation of the function of thrombin and autoprothrombin C in prothrombin activation. I know of no fact that is inconsistent with this analysis. Moreover, the reduction of plasma prothrombin concentration following vitamin K deficiency fully accounts for the decrease in the amount of autoprothrombin I, II, or III that can be derived from such plasma. One glance at the diagram of Figure 9 brings the realization that prothrombin activation can consist of many events at one time and that there is no sequence of events that can be insisted upon, except for one set of conditions. Work with purified clotting factors has, however, made it possible to study isolated reactions. From this information it is possible to construct such an integrated concept and claim validity for it. Short circuits, bypasses, and substitutions in such a system fully account for the infinite variations on the central theme of prothrombin activation. In rare cases even the prothrombin can be omitted as, for example, when snake venom clots fibrinogen directly.

Even though the summary of Figure 9 may seem complicated and is a description for only one set of conditions, it highlights fundamental principles and presents a concept which gives a student the foundation on which he can construct his working knowledge to deal with the individual variant. There are several outstanding facts.

Prothrombin is a molecular system or a multipotential molecule from which two enzymes, *thrombin* and *autoprothrombin C*, can be derived or from which other subunits can be obtained.

Whenever there are many prothrombin molecules, as under physiological conditions, a random prothrombin activation occurs which is representative of the particular conditions. One or another of the possible derivatives forms from one molecule. One or another of the possible derivatives forms from another molecule and so on to give the necessary impetus for getting an adequate amount of thrombin.

The antihemophilic factor (factor VIII, platelet cofactor I) first functions as a procoagulant and then as the receptor of an inhibitor which develops as a consequence of thrombin activity.

Autoprothrombin II is derived from prothrombin while the antihemophilic factor is still a procoagulant and being neutralized. It then serves as a relay to do the work begun by factor VIII.

Thrombin is the main activating enzyme in the platelet + plasma system; if autoprothrombin C is active the amounts are small.

Thrombin and autoprothrombin C are the activating enzymes in the platelet + plasma + tissue system.

The enzymes for prothrombin activation come from prothrombin itself and Ac-globulin functions as a coautocatalyst for these

enzymes. Ac-globulin regulates the reaction specificity of the two enzymes.

Other prothrombin derivatives act as accelerators for the conversion of prothrombin to thrombin. The lipoproteins serve as accelerators of the interactions by their surface activity. They supply hydrophobic and hydrophilic forces for orientation in the enzyme activities. Calcium ions are needed in the coordination chemistry. All of what is outlined on Figure 9 can be bypassed by retaining only prothrombin and obtaining thrombin with an enzyme such as trypsin, or other suitable enzymes, or just a strong salt solution such as sodium citrate.

Serum

Serum can be regarded as a product of blood clotting and contains the spent products of those reactions. Some of the molecules concerned may remain in their original form, while other activities develop and get neutralized. Serum may contain autoprothrombin III from the platelet + plasma activation environment. Autoprothrombin C, autoprothrombin I. and thrombin are inactivated by antithrombin, and must be in serum combined with this inhibitor. The concentration of antithrombin in serum is less than that in plasma. Any autoprothrombin II activity which generates remains in serum. Ac-globulin is found in the serum of some species but is masked in others. Platelet cofactor I is associated with an inhibitor; the procoagulant power of tissue extracts tends to be neutralized and is not present in serum. There are, of course, platelet remnants, serotonin, and split products from fibrinogen, platelet factor 3 from platelets, and perhaps a similar substance from any hemolyzed red cells.

Polymerization of Fibrinogen

As soon as thrombin has accumulated in sufficient quantity and participates in the many reactions, it also finds fibrinogen as a substrate. As a result of this function, the fibrin clot is formed. Many of the details of this chemistry have been so well described that it is perhaps the best known example to illustrate the way in which structures are formed in biology.

The enzyme thrombin, which is an endopeptidase, removes at least one and not more than four peptides from the six long peptide chains of the fibrinogen molecule (M.W. = 330,000). Cleavage occurs at a particular arginyl-glycine peptide bond. The fibrin monomer which remains consists of practically all the original fibrinogen molecule, because the split-off peptides are small, the molecular weight of peptide A being 1,900 and that of peptide B 2,460. Several of such fibrin monomers associate end-to-end when peptide A is gone and form strands. Side-to-side polymerization occurs when peptide B is split off so that the strands enlarge their width. Then with branching also occurring, the fibrin network is built up. Electronmicrographs of such a network consist of alternate light and dark bands spaced in such a way that there is correlation with the original structure of the fibrinogen molecule.

The fibrin which is produced in the laboratory by the polymerization of purified fibrinogen in the presence of purified thrombin is soluble in 5 M urea solution, but the natural fibrin is not. The reason for this difference is that thrombin has a further function in the formation of a clot. Thrombin activates a protein in plasma usually called fibrin stabilizing factor or fibrinase (M.W. = 350,000) which becomes activated by thrombin. The fibrinase itself perhaps becomes a part of the clot, for it is not found in serum to any appreciable extent. For the function of fibrinase in clot stabilization, calcium ions, or a divalent substitute, are needed. The stable fibrin clot is thus an advanced consolidation of the slightly modified fibrinogen which is in plasma.

Summary Fibrin Formation

For purposes of summarizing some of the basic enzymology in blood clotting, another diagram has been designed (Figure 10). It has many limitations which do not occur in Figure 9. The basic idea of prothrombin activation by autocatalysis is featured. The procoagulants, which are substances that promote thrombin generation, are listed. Likewise the anticoagulants, or substances which retard thrombin generation, are listed. Normally there exists a balance between procoagulant and anticoagulant forces.

Pathological Aspects

During the decades just passed, numerous irregularities in the blood-clotting mechanisms were discovered in hospitals and clinics. Ways and means were found to differentiate one abnormality from another, and in many instances effective therapeutic measures were employed. In other instances ways and means to provide help are still being sought for. Along with the clinical work, attempts were made to describe the nature of the underlying chemistry involved. A conspicuous error permeated the working rationale: it was assumed that a defined deficiency which differs from another is due to lack of a previously unknown clotting factor. Then the hypothetical factors were given numbers by the International Committee on the Nomenclature of Blood Clotting Factors. The next task is to differentiate between what was created by committee work and what was created by work in the laboratory. Already the biochemical aspects are outlined as described above and in other papers.[1-7] Since this represents basic chemistry, it subsumes the hypothesis advanced at the clinical level of observation, as stated recently.[8-12]

The following notes on pathological manifestations highlight most of the main problems. Irregularities in clotting can occur when fibrinogen is absent. Lack of the fibrin stabilizing factor is associated with an abnormal fibrin network. If there is a deficiency of vitamin K due to lack in the diet or faulty absorption, or if liver function is abnormal, very little prothrombin synthesis can occur in the liver, and prothrombin derivatives cannot be formed. Evidently factor VII, IX, and X deficiency are due to an abnormal prothrombin molecule. In parahemophilia there is a reduced plasma Ac-globulin concentration. In von Willebrand's disease there is a low concentration of platelet cofactor I (factor VIII), and also of a substance needed for hemostasis. In hemophilia A there is excess of an inhibitor, and not a lack of platelet cofactor I as was generally thought previously. Besides a reduction in platelet numbers there are conditions in which platelet factor 3 is absent or not released for its proper function. Factor XII deficiency apparently is not associated with a bleeding tendency. The severe complications in placenta abruptio bring changes in Ac-globulin, fibrinogen, factor VIII, and to a lesser extent in prothrombin. The clotting mechanisms are brought into play by bacterial endotoxins, trypsin, and snake venoms. In thrombosis, as a result of many conditions still to be described, fibrin deposits are involved.

Star-spangled savings plan

(How it can help you to a well-provided future)

Most of us think about the future in terms of our families—paying off the mortgage, educating the children, providing a retirement income.

But with the world the way it is today, it's almost impossible to make plans for your own future without considering the future of your country, too.

When you buy U. S. Savings Bonds, your money takes on both jobs. It begins to grow, surely and steadily, to help you reach your savings goals and build your financial strength.

At the same time, Uncle Sam uses these dollars to help reach our *national* goals of peace and security.

Why not give your savings dollars this double assignment? You'll be joining millions of American families who are investing in their country's future—and you'll probably find that you feel pretty good about the whole thing.

Buy U.S. Savings Bonds

STAR-SPANGLED SAVINGS PLAN
FOR ALL AMERICANS

Medicine and Religion

Schweitzer on the Paranoia of Jesus

Albert Schweitzer is remembered as theologian and physician. Yet it is seldom realized the importance his medical studies had for his theological research at one point. This was in his M.D. thesis, *The Psychiatric Study of Jesus: Exposition and Criticism,* 1913. Schweitzer was dealing with a question of importance to both physician and theologian. What is the relationship between religious faith and mental illness? If religious experience, especially that of great religious leaders, derives partially from psychopathology, can the ethic and religion based on such experiences be an appropriate guide for life? This question was cast in its most controversial form when focused on the person of Jesus. This had been done early in this century by the work of three psychiatrists: George Lomer (who wrote under the pseudonym de Loosten), William Hirsch and Charles Binet-Sangle. These writers were influenced by the work of Emil Kraeplin on paranoia, which provided the theoretical basis for the study of Jesus' life and thought as an example of psychopathology. While they differed as to the etiology and progress of the disease, they all concluded that Jesus suffered from severe paranoia characterized by visual and auditory hallucinations; that the disease was marked by progressive deterioration in which Jesus increasingly identified himself as a divine being who would bring in the Kingdom of God.

To understand such an interpretation of Jesus and Schweitzer's response to it, it is necessary to recall two intellectual developments of the nineteenth century: First, the rise of an undogmatic, historical study of Jesus and the origins of Christianity; Second, the development of psychoanalytic psychology. Paradoxically, it was the new historical research that raised in heightened form the question of Jesus' mental state. Since the work of D. F. Strauss, 1835, historians had recognized the importance for Jesus of the apocalyptic ideas drawn from Judaism which focused on the imminent end of the world. Schweitzer in his earlier book, *The Quest for the Historical Jesus,* had shown that Jesus thought of himself as a central figure in the drama of the end times. So it was not surprising that many looked to Schweitzer to absolve Jesus of the paranoia which had been assigned to Him by the psychiatric interpreters.

Schweitzer worked for a year on his brief monograph relating to the new literature on paranoia as it pertains to the complexities of the New Testament. He uncovered two underlying fallacies in the work of de Loosten, Hirsch and Binet-Sangle. First, their historical analysis was inaccurate: they treated the Gospels as if they were verbatim reports of the sayings of Jesus. Actually, the Gospels represent an expansion upon the sayings of Jesus. The claim of Hirsch that Jesus' preaching culminates in one word:

Continued

"I," represents an uncritical reading of the markedly unhistorical Gospel of John. It is an assertion that will not be supported by comparison with the Synoptic Gospels. Second, these interpreters had failed to understand Jesus' relation to the religious world-view of his contemporaries. Jesus' ministry was not shaped out of a set of delusions he developed himself but from the context of contemporary religion. The expectation of the end of the world, demonic and angelic intervention in human affairs, and the coming of messianic deliverers were all part of the then normative conception of reality. Jesus' presentation of himself as a key figure in the drama of the end times has a rationality in light of its contemporary world-view, which it lacks in our own. The participation of a man of the first century in the religious ideas of his time is no proof of his insanity no matter how bizarre the ideas seem to modern men. While Schweitzer demonstrated the work of the psychiatric interpreters to be vitiated by historical misunderstanding, he also recognized they had raised an important issue. Can a man of the past, emerging within a conception of reality foreign to our own, provide a guide in religion and ethics? Specifically, can Jesus, the apocalyptic visionary of the first century, guide a man of the twentieth? His answer was, "Yes." Paradoxically, Schweitzer believed the abiding importance of Jesus derived from his coming to us from outside our culture. The apocalyptic vision of Jesus is important because it forces men to look beyond the limitations of their own time and place to seek new moral alternatives. The vision of a world under judgment, of a world nearing its end, reminds men of the smallness of their life goals and values. It is a vision that calls the religiously and ethically serious man to seek ever new means for service. In this light Schweitzer redirected his own life, so he could say, "I came to Africa in obedience to the call of Jesus."

On Gathering Simples

That the plucking of herbs and digging up of roots was a process very apt to be attended by magical procedure we find abundant evidence in Pliny's Natural History. A common instruction is to pick the plant with the thumb and fourth finger of the left hand; or the right hand should be stretched covertly after the fashion of a pickpocket through the left sleeve in order to pluck the plant. Sometimes one faces east in plucking herbs; sometimes, west; again one is careful not to face the wind. Sometimes the gatherer must not glance behind him. Sometimes he must fast before he takes the plant from the ground; again he must observe a state of chastity. Sometimes he should be barefoot and clothed in white; again he should remove every stitch of clothing. Often the plant must not touch the ground again after it is picked, presumably from a fear that its virtue would run off like an electric current.*

FILTER QUEEN

Proof? See inside—

DRAMATIC TEST PROVES FILTER QUEEN TRAPS

1 Place a fresh Sanitary Filter Cone in the FILTER QUEEN container. (It takes only a moment to open the machine and replace the old Filter Cone.)

2 Now unfold a clean white handkerchief and drop it into the Sanitary Filter Cone. (Even the daintiest, sheerest handkerchief may be used with perfect safety.) Then replace the turret top on the container.

3 Now turn the machine over to any one witnessing the demonstration, and have her start the machine and apply the nozzle to any place where there is obvious dirt and dust. Keep the machine operating for a full minute.

See the proof with the FILTER QUEEN *"clean handkerchief" test*

4 Remove the top of the container, and lift out the handkerchief. You'll find it spotless as it was when it went in! (Where did the dirt go? Look in the bottom of the container.)

NO DUST ON HANDKERCHIEF

filter traps dirt in container

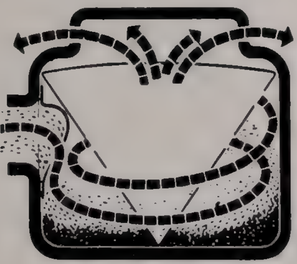
DUST AS NO "VACUUM CLEANER" CAN!

Revolutionary...and in a class by itself!
FILTER QUEEN
has the scientific cleaning features that hospitals need most

All "vacuum" cleaners were much the same until the FILTER QUEEN SANITATION SYSTEM was designed. FILTER QUEEN'S patented Sanitary Filter Cone eliminates the need for messy bags, traps practically all airborne contaminants passing into the machine (Harvard Medical School Report in Journal of the American Medical Association, November 25, 1958).*

Experienced hospital housekeepers know this well. That is why FILTER QUEENS have replaced every type of vacuum cleaner in hundreds of hospitals throughout the world.

FILTER QUEEN has no porous bag that permits dust and dirt to reenter the room. FILTER QUEEN operates on an entirely different principle, "Cyclonic Cleaning Action." Here's how it works: Inrushing air, laden with dirt and dust, is deflected by a patented inlet guide as it enters the container; then is whirled by centrifugal force away from the cone. Dust and dirt are dropped to the bottom of the container. (See illustration.) Air, being lighter, is funnelled to the center of the "cyclone," filters through the Sanitary Filter Cone and returns to the room dust-free.



Why not ask your local FILTER QUEEN Distributor to make the dramatic handkerchief test (pictured at left) in your hospital? There is no better way to prove the improvement in cleaning ability between a FILTER QUEEN SANITATION SYSTEM and any type of vacuum cleaner. (You'll find your distributor listed in the Yellow Pages; or write Health-Mor, Inc. direct).

We will be glad to send you a reprint of this report on request.

What hospital administrators say about FILTER QUEEN

"I heartily recommend to any hospital administrator who is presently unhappy with the type of cleaning machine in use, that he try FILTER QUEEN for only two days and the machine will sell itself."

"The FILTER QUEEN is great—a very important factor in patient areas, and is constructed so as to prevent air turbulence of dust at floor level. Filtering of the air, while in general operation, is also a very important and desirable factor."

"One of the most pleasing features of the machine is its quietness. We can even clean in the rooms while occupied by the patients, and many have commented on how pleasant it is not to be disturbed by noisy, old-fashioned vacuum cleaners anymore."

"The air exhaust at the top of the unit is a wonderful feature, and the Sanitary Filter Cone is certainly our answer for working in closely confined patient areas."

"We thought we had a clean hospital and a fairly good method of achieving acceptable sanitation, but this little machine made us revise our thinking and our methods."

"A quiet motor which possesses excellent cleaning power and the convenience of having to clean out the cleaning compartment only once a month, has proved very advantageous. One of the most important points . . . is that there is no bag to empty."

SOME PEOPLE KILL THEMSELVES TRYING TO GET TO WORK ON TIME

Getting your employees to and from work alive is a full-time job. *Yours.* And it's not just a matter of public welfare, either. Off-the-job traffic accidents cost American industry millions of dollars in lost time, training and production every year. Last year alone, more than twenty thousand workers were killed in off-job motor vehicle accidents. And more than 750,000 were injured. Motor vehicle accidents claimed more than 1½ times as many lives as on-the-job accidents. Can you do something about it? You really can't afford not to. Write now, to the National Safety Council for information on what you and your company can do. Address your letter to the Director of Public Information, National Safety Council, 425 N. Michigan Avenue, Chicago, Illinois 60611. *Published to save lives in cooperation with The Advertising Council and the National Safety Council.*

History of Medicine

Avicenna, The Prince of Physicians[*]

Part II

RAYMOND D. CLEMENTS, Ph.D.[**]
Bethesda, Maryland

The Humors

Avicenna's concept of the humors was essentially Galen's. Healthy humor was that moist substance which replaced the loss which the body substance underwent. The residue, or superfluity, was called unhealthy humor. There were four body fluids or humors, namely: sanguineous or hot-moist; serous or cold-moist; bilious or hot-dry; and atrabilious or cold-dry. These, in turn, could be normal or abnormal in varying degrees. Avicenna felt that Galen was wrong in holding all the humors but blood as superfluities; but the reasoning for his disagreement with Galen was purely dialectical; e. g., if the serous humor did not nourish the brain, the brain would not be soft.

His division of the bodily members included the bone, cartilage, nerves, tendons, ligaments, arteries, membranes and flesh. Each member in turn possessed at least the vegetative faculty, i.e., the powers of attraction, assimilation, expulsion and growth. This type of dialectical reasoning and classification formed the substructure of his medical theory as well as that of the European schoolmen after him. Suffice it to say that his dialectical approach quite naturally possessed the weakness of becoming progressively more detached from actual observation.

It is often difficult to ascertain in such authors as Avicenna what was the result of clinical observation and what the result of purely abstract reasoning, particularly since any clinical observations were consistently analyzed by the traditional facultative and humoral anatomy and pathology.

Metabolism

Avicenna, as Galen, Aristotle and others before him, always began his analysis of the human body with the vegetative faculty or what we might today call the process of nutrition or, more cautiously, 'metabolism.' He regarded this as primarily a four-stage process of breaking down food into chyle by means of the heat and the excessive moisture of the surrounding visceral organs.

The Nutriment

The chyle passed into the intestine, then was drawn off by the mesenteric vessels into the portal vein, thence into the liver, which manufactured the blood and carried the nutriment into the superior vena cava. At the same time, excessive moisture from the liver along with blood 'fat' and some blood passed into the kidneys. The blood manufactured by the liver was conveyed along into smaller and smaller cavities until it 'sweated' out, i.e., until it reached each portion of every member including the skin. While in the veins, the nutriment underwent a third digestion and, upon reaching a member, underwent a fourth digestion during assimilation.

Continued

The Waste Products

Waste products from the first digestion passed out through the intestines; those from the second digestion in the liver passed out chiefly by the urine, but also by the spleen and gall bladder. The waste from the third and fourth digestions passed out by perspiration, sordes, nostrils, ears, invisible pores, or through suppurations.

The Principal Organs

The principal organs were held to be the brain, heart, liver, and reproductive 'gland.' The afferent organs were the sense organs, lungs, stomach, intestines, veins, and constituents of humors. The efferent organs were the nerves, arteries, gallbladder, spleen, kidneys, ducts and genital adnexa. The elementary tissues included the bones, cartilages, ligaments, muscles, fasciae, tendons, membranes, flesh, fat and intestinal tract. The members, in Avicenna's system, could also be classified according to their origin, e. g., from the blood or sperm. He recognized the existence of tissue or fiber layers in the blood vessels, intestines and muscles. He seemed to recognize the existence of blood in the arteries but thought that their primary function was to carry the 'breath.' Strong members expelled their waste matter into weaker members, e. g., the brain to the tissues behind the ears.

Unfortunately, his anatomical knowledge did not exhibit any details that could have come from animal dissection, much less postmortems. In this respect, he was inferior to Galen, whose culture as least permitted vivisection of a pig. The Islamic culture, as well as the Judaic and the Christian cultures until the thirteenth century, did not permit human dissections.

The Stages of Disease

In his pathology Avicenna resorted to logical distinctions of causes, symptoms, signs, etc. In other words, he employed the arguments of logical causality to differentiate cause from symptom, symptom from sign, without bothering to discuss the actual disease phenomena. He recognized four stages of disease: onset, increment, acme and decline. Diseases could be named according to the member affected, the chief symptom, the originating humor, the resemblance to animals, the first historical example, or according to the essential nature of the disease (e. g., fever).

Epidemiology

In his discussion of epidemiology, he included, under transmission by infection, the notion that eye diseases could be transmitted by a gaze. He also recognized hereditary, racial, endemic, and atmospheric transmission. His descriptions of the role of the atmosphere, seasons and climate were traditional from Hippocrates. His discussion of how these factors influenced health was a restatement of the theory of the interaction of the four elemental qualities of hot, cold, wet, dry, and the correlative humors and temperaments.

His notions of dietetics were likewise a restatement of traditional views found in Galen and Paul of Aegina, the seventh century Byzantine compiler. Interestingly, he included a lengthy section on water in which he recommended purification by boiling, sublimation and distillation. He noted that, excluding climatological factors affecting health, the body could also be influenced by external agents which are not injurious *per se.* For example, the body could absorb the primary quality of an application such as a plaster through the pores, or there could be a combination of external and internal qualitative changes. His concept of balneology continued this fundamental notion of the role of external agents producing qualitative changes by altering the balance of the four elemental qualities.

Pain

In his concept of pain, he professed to disagree with Galen in attributing loss of continuity to be a primary cause of pain. He felt that pain was rather a transmutation of the temperament of the affected part. In this connection, he listed 15 different types of pain. The causes he assigned for these pains were again consistent with his four elemental qualities, with the consequence that alleviation of pain was by counteraction.

Signs and Symptoms

His discussion of diagnosis by signs and symptoms was also consistent with the four-qualities theory. His main contribution was perhaps a greater emphasis on tabulation. In our age of laboratory analysis, x-rays, and other techniques to determine the nature of a patient's health or illness, it is difficult to appreciate the enormous store which Avicenna and those following him placed on feeling the pulse, on uroscopy, and on fecal examination. While such examinations were employed at least as far back as Galen and even basically noted in the Hippocratic writings, by Avicenna's time they had become codified into a 'science,' requiring lengthy tabulations of tactile (pulse), visual and odor (urine and fecal) qualities. The urine flask being examined by the doctor became the standard art symbolism of Avicenna's medieval successors.

The Pulse

Avicenna listed 11 basic types of irregular pulse. These were considered the simple pulses and could, in turn, again be subdivided into compounds; but he felt the subdivisions were too numerous to list. There were basically three contentive factors in producing the pulse: the vital power of the heart, arterial elasticity and arterial resistance. These in turn could be subdivided into essential and nonessential, and again redivided. Pulse could also be related to age, temperature, season, emotions, habits, temperaments, and locations.

Uroscopy

As did pulse lore, so did uroscopy in Avicenna reach a high degree of tabulation. The basic philosophy of uroscopy was primarily to determine liver function, i.e., the functioning of the liver as a second agent in metabolism and hematopoiesis. Secondarily, the examination was to determine the state of the urinary passages and blood vessels. The urine was examined for quantity, odor, color, foam, texture, clearness, and sediment; we cannot profess to evaluate the number of visual qualities which Avicenna listed. Suffice it to say, however, that he believed such qualities could be correlated with the four elemental qualities of the humors as they

Continued

are expressed in his pathology. He professed to be able to differentiate, among other things, pregnancy, sex and age, cerebral disorders, jaundice, and human and animal urine. Except for sterilizing the bottle, the method of collection was about as precise as today. There was also a prescribed regimen to be followed before giving the specimen, as well as a precise time for collecting it.

Fecal Examination

Fecal discharges were examined for quantity, consistency, color, form or shape, and time occupied in passage. Findings were also correlated in tabular form according to the humoral pathology.

In his total view of the life process, he repeated in condensed form various traditional notions, such as death being the extinguishing of the innate heat, and the male sperm being the formative agent while the female provided the matter for generation.

The Specialties

In his concept of nutrition, following traditional lines, he began with pediatrics and continued the discussion through geriatrics. These topics were also treated according to the humoral concept of establishing the right temperament for the right age. In his pediatrics, he covered teething, convulsions, night terrors, brain inflammations, ear-nose-and-throat disorders, respiratory and digestive disturbances, hernia, worms, skin disorders and fevers. In discussing regimen from infancy to adolescence, he insisted that the one great principle was the inculcation of emotional control. This was to be accomplished by removing all emotional irritants so that the mind could grow free from anxiety.

In discussing adult regimen and exercise, he reflected to a great extent what must have been the high cultural level of his times by his constant references to the public bath houses and varieties of wines. In this connection, he also prescribed anti-inebriants and restoratives. He recognized hepatic and nerve damage from excessive drinking. He also discussed anesthesia, including wine, opium, nerve depressants (aloes), and narcotics (mandragora and darnel).

Therapeutic Measures

His therapeutic measures included purgatives, emetics, cupping, venesection, leeches, liniments, and minor surgery. Consistent with his general medical theory, he envisioned therapy as being the physician's attempt to restore the balance in the temperaments. He employed a logical scheme for treating by opposites, e. g., plethora by depletion. These techniques were accompanied by detailed rules.

Purgatives

Before administering a purgative, the physician had first to determine which of the humors were at fault, how to prepare the body for the purge, and who should or should not be given purges. An example of the latter was the notion that people who lisp were liable to gastrointestinal catarrh and therefore could not stand strong purges. Avicenna probably also had occasion to treat impacted feces, since he pointed out the danger of using purges in their presence, and recommended instead enemas and emollient broths. As with purgatives, Avicenna also gave detailed rules for emetics, much of which appears to have been taken from Paul of Aegina and Rhazes.

Venesection

Venesection was to be resorted to in order to remove excessive humors present in the blood vessels, and was to be resorted to either when the blood was so superabundant that a disease was about to develop or when the disease was already present. If the disease was already present, bloodletting could be resorted to only after the acme of the disease had been passed. Cupping was envisioned as a method of cleansing a particular area of the skin more effectively than bloodletting by drawing off the more rarefied rather than the more viscid blood. It was used to draw out deep inflammations, to divert an inflammation to a neighboring part, to restore a member to its proper position, or to allay pain. The points of application and the corresponding therapeutic uses were also tabulated.

Leeching

Leeches were used to withdraw blood deeper down than that which could be obtained by wet cupping. Inflammatory swellings were treated by astringents, resolvents, refrigerants, venesections or purgatives, depending on their humoral cause. Cautery was recommended for gangrenous ulcers, preventing the spread of a destructive lesion, rectifying the cold temperament of a member, breaking up putrefactive matters imprisoned in a tissue, or controlling hemorrhage.

Priority of therapeutic measures was guided by three principles:

(1) When one malady had to be cured before the other could be relieved.

(2) When maladies were related as cause and effect.

(3) When it was absolutely essential to deal with one of the maladies, even though the other may not have been relieved by the treatment.

Psychology

Avicenna, as other Islamic and European medieval writers following the Aristotelian tradition, did not of course use the term ‘psychology’ but rather the term ‘soul.’ The term ‘soul,’ however, did not have a purely religious meaning, nor was it merely some ethereal principle leaving us at death. Rather Avicenna’s concern with ‘soul’ represented a serious exercise in reasoning to determine the differences between a simple organism and a human organism. As others in this tradition, he attempted to differentiate levels of ‘soul’ by means of vegetative, sentient, and reasoning faculties. He further wanted to differentiate between creatures with a reasoning faculty (man) and creatures who must, by the laws of the Aristotelian logical causality, exist prior in some manner to man. In this respect, unlike Averrhoes, he preserved the religious orthodoxy of his psychology by insisting on the individuation of the human soul apart from the heavenly ‘active intellect’ or ‘world soul.’ Moreover, he showed much concern with what we would term ‘physiological psychology.’ This concern was expressed by dwelling on the ‘motive’ aspects of the soul, i.e., the emotions, the vital breath, and why the emotions were expressed by particular bodily aspects. That his reasoning was completely dominated by his Aristotelian logic and the humoral theory does not negate

Continued

the fact that it was this emphasis or interest that was later to be picked up by Vives, Descartes, and others until it found expression in the 'dynamics' and 'associationism' of modern psychology.

History of Medicine in Wright County*

In 1879 **Dr. Neil Downey** of Minneapolis announced that he would come to give dental services for five days. He offered to take on any dental work. It seems he did not continue this for very long. In February, 1880, **Dr. E. Pentecost**, a dentist of Willmar, Kandiyohi County, offered his services in Delano — "prepared to practice dentistry in all its branches."

In the summer of 1881 **Dr. Jewett** of Minneapolis promised regular visits to Delano, and in the same year **Dr. S. C. Carter's** name appears. Dr. Carter was a heavy advertiser and remained much longer than practically any of those mentioned so far. He was, no doubt, a resident dentist in the early 1880s. In 1883 he resided in Howard Lake and visited Delano on the third Wednesday and Thursday of each month, practicing at Young's Hotel. From 1887 on, or even earlier, he had his office in Minneapolis, coming for two days to Maple Plain, for the same period to Delano and Waverly and for only one day to Montrose. The first three days of each week he reserved for his Minneapolis clientele. In 1888 he allocated two days to Delano, one to Montrose and three to Watertown, Carver County. Late in 1889 his card read "Dr. and Mrs. Carter, dentists Minneapolis."

In 1882 several dentists tried their luck in Wright County. In April **Dr. R. R. Todd** opened dental rooms in Hank Ball's Gallery in Delano in order to practice a week or so at a time in that town and in Waverly, but also in Watertown, Carver County. He promised painless extractions and "prices as low as the lowest." In August **Dr. L. M. V. Russell** announced his plans to come to Buffalo and Delano. In the latter town he would practice the last week of every month. In October **Dr. Holden** announced his services in Monticello.

In August 1883 **Dr. N. Ellis and Son** of St. Paul announced their plans of practicing in Delano and Rockford, perhaps as long as a week at a time. "Teeth extracted without the least pain or injury by the use of vitalized air. Artificial teeth from one to an entire set; a perfect fit is given in every case or no pay." In Delano they used first the Danforth House and later the Centennial Hotel. Soon they included Monticello in their circuit.

From 1884 to the end of the decade **Dr. W. Niven** of the firm **Morgan and Niven**, Minneapolis, advertised as "Painless Dentist" and "Teeth extracted by use of Nitrous Oxide or Ether. Special attention to preservation of natural teeth with gold, silver, and cement fillings. Intends to come periodically." He practiced in Rockford and Buffalo and also in Watertown, Carver County, and stayed at times as long as a week. In Delano he usually stayed at the Danforth House. Early in 1885 a **Dr. McKeel** announced his intentions of regular visits to Delano.

Medical Economics

What's Doing in Washington...

Health Legislation Record Set by 89th Congress

More and farther-reaching health legislation was enacted into law in 1965 than ever was enacted by a previous Congress.

Medicare and the heart disease, cancer and stroke programs topped the list of such legislation enacted into law, but there also were other important new health programs authorized. Several existing ones were expanded.

Approved health legislation included:

—A $787 million aid program for medical, pharmaceutical and other health schools. It authorized for the first time federal scholarships for students and operating funds for medical schools.

—A $105 million program of aid for medical libraries.

—A $250 million, three-year extension of grants for construction of health research facilities.

—Authorization of strict federal controls on manufacture and sale of barbiturates and amphetamines.

—Requirement that cigarette packages, beginning January 1, 1966, carry a health hazard warning.

—Extension of the vaccination program and expansion of it to include measles.

—Annual appropriation of a record $1.2 billion for the National Institutes of Health.

—Three new assistant secretaries of Health, Education and Welfare — one for health affairs.

—A four-year $92.5 million program of aid to municipalities for construction of garbage disposal plants and research in the field.

—Greater federal powers in the water pollution field, and $300 million to help communities build sewage plants.

—New federal powers to control air pollution, including requirement that new autos have devices to reduce exhaust fumes.

—Expansion of the federal vocational rehabilitation program, including $300 million in grants for building and initial staffing of rehabilitation facilities and workshops.

—A four-year $173 million program for initial staffing of community health centers.

—An administration on aging in the Health, Education and Welfare Department.

—Appropriation of $157 million for "Project Headstart" — nursery school training and medical examinations of pre-grammar school children from low-income families.

—A $69 million hospital program for the Appalachian area.

—Automatic rank of lieutenant general or

Continued

vice admiral for surgeons general of the army, navy, and air force.

—Extension for three years of the program of grants for health services for domestic migrant agricultural workers.

—A one-year extension of program of grants for general health aid and for community health services.

Federal Agencies Take Antihistamine-Patent Medicine Stand

Federal agencies relaxed regulations for the sale of Ipecac, ordered warning labels on certain antihistamines and cracked down on two patent medicines.

The Food and Drug Administration decided that ready availability of Ipecac as a poison remedy outweighed the dangers of possible misuse and placed it back on the list of drugs for sale over the counter without a prescription.

Since Ipecac was placed on a prescription-only basis in January, 1964, the American Medical Association, the American Academy of Pediatrics and the Association of Poison Control Centers had urged that the vomit-inducing drug be returned to its former status.

Under the new FDA ruling, FDA's Bureau of Medicine told the pediatrics group in Chicago that FDA decided it would be in the public interest to permit Ipecac to be sold over the counter in one-fluid-ounce bottles with special warnings on dangers of its misuse.

The FDA also ruled that in the future antihistamines containing meclizine, cyclizine and chloro-cyclizine must bear labels warning against use by pregnant women without medical advice. However, they were left on the over-the-counter list. The FDA said massive doses of these drugs in test animals had produced congenital abnormalities, but there had been no evidence they have caused abnormalities in human babies.

Chas. Pfizer & Co., Inc., one of the companies that manufacture such antihistamines, protested the decision as not being "in accordance with the medical facts."

A House Government Operations Subcommittee headed by Rep. H. L. Fountain (D., N. C.) recently had criticized the FDA for its handling of these antihistamines, contending that stronger warnings were needed and indicating that they should be prescription items.

The FDA ordered a halt to the sale of Alergimist "A" and "B," widely advertised as "cures" for hayfever, bronchial asthma, migraine headaches and allergic dermatitis.

The product has been actively promoted through newspaper, radio and television ads without having been passed by the agency as either safe or effective. The product, sold without a prescription, was being distributed by the Brunson Corporation of Miami Springs, Florida. FDA said the same concern previously distributed Allergimist (with two "l"s) until an injunction in September, 1964, was obtained against its interstate shipment.

The Federal Trade Commission ordered the J. B. Williams Co. of New York City to stop allegedly misrepresenting the effectiveness of "Geritol" liquid and tablets. The Commission ruled that Geritol television commercials and newspaper advertisements falsely represent that all cases of tiredness, loss of strength, run-down feeling, nervousness and irritability indicate a deficiency of iron and that the common, effective remedy for these symptoms is Geritol.

Geritol is not beneficial except in the small minority of persons whose tiredness symptoms are caused by a deficiency of iron or one or more of the vitamins contained in the preparation, the FTC said.

A sufficient and sure method of civilization is the influence of good women.

— Emerson

Medical Education

14 New Medical Schools Seen Within Five Years

Fourteen new medical schools are expected to be in operation in the United States by 1970.

These will bring to 101 the nation's total of schools of medicine and mark an "era of major expansion" in American medical education, according to the November 15th issue of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

"Of obvious and immediate importance is the fact that 800 to 1,000 new positions will be available to qualified medical applicants," the Journal said. "This will help to meet the urgent national need for more physicians."

In addition to these 14 firm commitments to build schools, at least ten other institutions "seem to be reasonably good possibilities to follow through with the development of a new (medical) school," the Journal said.

The new medical schools are but one of the indicators that American medical education is expanding.

The 65th annual report on medical education by the AMA's Council on Education appeared in the November 15th issue of the Journal. The report contains data which mark continuing gains in graduate medical education, continuing medical education, educational programs in areas allied to medicine and programs of government agencies pertinent to medical education.

All of the new medical schools will introduce modifications of the standard medical curriculum. This should lead to "some very interesting experiments in medical education," said the Journal. The new schools also will be competing for faculty with existing schools.

"This will certainly aggravate an existing manpower problem, but it will also open up new opportunities for leadership to young, vigorous medical scientists," the Journal said.

Over the past 20 years, the number of medical schools has increased steadily from 77 schools in 1945 to 88 in 1965. The next five years, however, will mark the period of greatest expansion. Eight of the 14 schools being planned will provide full four-year programs leading to the M.D. degree. The other six are envisioned as two-year schools of the basic medical sciences.

"However, three or four of the latter may well progress directly to four-year programs after they have become firmly established," the Journal said.

The four year schools: The University of Arizona College of Medicine, Tucson; University of California School of Medicine, San Diego; University of Connecticut School of Medicine, Farmington; Milton S. Hershey Center, Pennsylvania State University, Hershey; Mt. Sinai School of Medicine, New York City; South Texas Medical School, University of Texas, San Antonio; University of Massachusetts and Toledo State College of Medicine, Toledo, Ohio.

The two-year schools: Brown University Program in Medical Science, Providence, Rhode Island; University of Hawaii Medical School, Honolulu; Michigan State University College of Human Medicine, East Lansing; Rutgers University Medical School, New Brunswick, New Jersey; University of California at Davis and the University of New Mexico School of Medicine, Albuquerque.

The University of New Mexico accepted

Continued

its first class in September 1964. As a developing two-year school, it becomes eligible for full accreditation when its first class nears the end of the sophomore year.

Rutgers expects to admit a small class in September 1966. Arizona, Brown, Hawaii, Hershey, Michigan State and South Texas are planning to begin in 1967. All of the 14 schools should be in operation by 1969 or 1970.

Postgraduate Medical Education Expanding

Most physicians continue to study medicine long after entering practice, and the number of postgraduate medical courses available to them has increased nearly 50 per cent in the past five years.

This year, 1,641 courses are being offered in 40 states and the District of Columbia, reports the November 15th JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION which contains the 65th annual report on medical education by the AMA's Council on Education. The number of physicians registered in these courses may be over 150,000.

Attending courses, however, is only one of the ways a doctor continues his education. Most physicians rank their continued reading of medical literature as one of their most important sources of new knowledge. They also continue their education through professional contacts with other physicians and through hospital staff meetings and national, state and local medical society meetings.

Formal postgraduate courses, however, are becoming increasingly important. Medical schools continue to be the major sponsors, but courses also are offered or co-sponsored by medical societies, voluntary health agencies, hospitals and governmental health agencies.

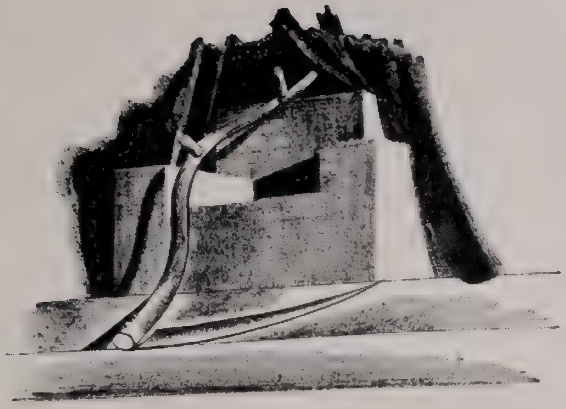
The most popular subject when doctors return to class? Psychiatry, by a wide margin. Courses in general medicine come next. Special subject areas such as pathology, surgery, ophthalmology, obstetrics-gynecology and cardiovascular disease also are popular.

Figures are not now available on the total number of physicians attending continuing education courses. Partial figures indicate that there has been a marked increase since last year.

During the 1964-65 academic year, there were 88,845 registrations at courses sponsored by medical schools. Medical schools sponsor about half the courses. If attendance at other courses was similar, the total registration last year must have exceeded 150,000, the report said.

The Nasturtium

Albertus Magnus (1193-1280), expatiating on the therapeutic virtues of the nasturtium, said: "It possesses acidity, is hot and dry, acts as a gentle purgative and laxative, and dries up the putridity of an empty belly. Used as a potion and liniment, it keeps the hair from falling out. Combined with salt and water, it helps abscesses and carbuncles, and mixed with honey, it eradicates Persian Fire and is good for all softening of the muscles. It purifies the lungs and relieves asthma by its sharp, cutting qualities. It warms the stomach and liver and cures enlarged spleen, but its disturbing quality is bad for the stomach. It is good for venomous bites, and if carefully prepared, works many other effects."



In Memoriam

Death will be what health is to the sick man; what home is to the exile; what the loved one given back is to the bereaved. — Fuller

ROSCOE C. HUNT, M.D.

Dr. Roscoe C. Hunt, 82, life-long Fairmont physician and surgeon, died November 13, at a nursing home at Rhinelander, Wisconsin. He was born in Fairmont and received his degree of medicine from the Harvard Medical College.

He was a member of the American College of Surgeons, the Blue Earth Valley Medical Society, and the American Medical Association. Dr. Hunt was a 50 Club and life member of the Minnesota State Medical Association. It was Dr. Hunt and his father, Dr. F. N. Hunt, who founded the Hunt Clinic which now is the Lakeside Clinic in Fairmont.

He is survived by his wife, two daughters, and two sons, Dr. Robert Hunt of Portland, Oregon, and Dr. William Hunt of Danville, Pa.

HAROLD H. JOFFE, M.D.

Dr. Harold H. Joffe, 54, Virginia pathologist, died September 30, en route from his home to the hospital. He was born in Chicago and was a graduate of the University of Illinois Medical School.

He was a member of the American Clinical Pathologists, College of American Pathologists, Minnesota Society of Clinical Pathologists, American Medical Association, Minnesota Medical Association, Range Medical Society, Virginia Chamber of Commerce health committee, and the Masonic Lodge.

He is survived by his wife, a daughter and two sons.

ALMER M. AANES, M.D.

Dr. Almer M. Aanes, 79, former Goodhue county health officer and a physician for more than fifty years, died November 28. He was born in Clermont, Iowa, and obtained his medical degree at the University of Iowa.

For twenty-five years, Dr. Aanes was a surgeon for the Milwaukee Railway. He was an organizer of the North American Life and Casualty Insurance Company and a member of its board of directors for many years. He was a member of the American Medical Association, Goodhue County Medical Society, and a 50 Club and associate member of the Minnesota State Medical Association.

He is survived by his wife, a daughter, and a son, Dr. A. Russell Aanes of Tucson.

JOHN EDWARD TWOMEY, M.D.

Dr. John E. Twomey, 45, chief of staff at St. Mary's Hospital in Minneapolis since 1962, died November 30. He was born in Brockway, Minnesota, and graduated from the University of Minnesota Medical School.

Dr. Twomey was a clinical instructor in surgery at the University of Minnesota, served on the Glen Lake Sanatorium Commission, the General Hospital and Health Advisory Board, and the board of the Minneapolis War Memorial Blood Bank. Under his chairmanship, a cancer clinical research program and tumor registry was initiated at St. Mary's in 1959. He was a member of the American Medical Association, Minnesota State Medical Association and Hennepin County Medical Society.

He is survived by his wife, a daughter and three sons.

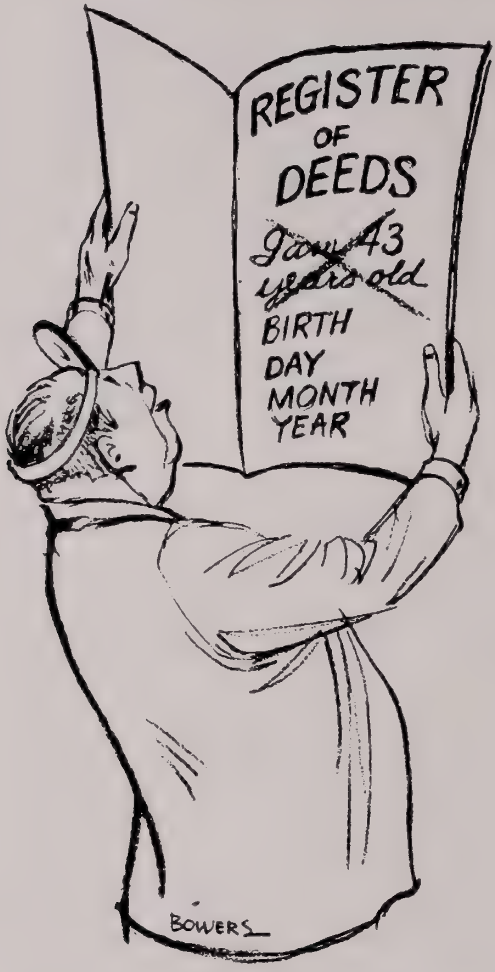
FLOYD A. THOMPSON, M.D.

Dr. Floyd A. Thompson, 62, St. Paul pediatrician, died November 24, after a lengthy illness. Born in Minneapolis, he had resided in St. Paul fifty-five years, and practiced medicine there for thirty-four years.

He received his medical degree from the University of Minnesota, and was a former chief-of-staff at St. Lukes Hospital in St. Paul. He was a member of the Academy of General Practice, American Medical Association, Minnesota State Medical Association and Ramsey County Medical Society.

He is survived by his wife.

Better Service, Doctor?



Only Jack Benny gets away with being 39 all his life. He doesn't even use a birth date.

But in our efforts to improve service to our participating physicians and their patients, Blue Shield must have accurate birth dates on all claims for payment.

In fact, if your patient is a member of such groups as Federal Employees, Steel and/or J-Group, we cannot even begin to process the claim without the exact birth date.

Payment for incomplete reports might be delayed . . . or rejected. **Help us help you!**

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of MINNESOTA MEDICINE, *496 Lowry Medical Arts Bldg., St. Paul, Minn. 55102*

PHYSICIAN — TB and Geriatric State Hospital; accredited; $12,828.00-$15,600.00 based on qualifications and experience; desirable suburban location; residence available; liberal sick leave and vacation benefits; excellent retirement system. Contact: Medical Director, Glen Lake State Sanatorium, Minnetonka, Minnesota.

TWO G.P.'s NEEDED — Northern Minnesota county seat. New hospital, office space available, two other physicians in town, anesthetist on hospital staff, good schools, all churches, excellent hunting and fishing, housing available. Full details upon request. Contact: Administrator, Roseau Area Hospital, Roseau, Minnesota.

BADLY NEEDED — G.P., Internist or Surgeon to associate with two-man G.P. partnership. Unopposed territory. New hospital, nursing home, children's home! Superb hunting, fishing, golf, pool, winter arena. Progressive town! Delmore Clinic, Roseau, Minnesota 56751.

PART TIME INTERNIST OR GENERAL PRACTITIONER. Good compensation — Midway Area. Alfred F. Anderegg, M.D.; 2500 Como Avenue, St. Paul, Minnesota.

WANTED: Board Certified or eligible internist to associate with group in large, active practice in Minneapolis. Group consists of Surgeon, Obstetrician, Pediatrician and Internist maintaining downtown and suburban offices. Partnership in mind. Contact: Jesse J. Barron, M.D., 1127 Medical Arts Building, Minneapolis, Minnesota 55402, FEderal 2-8259.

OLD, WELL ESTABLISHED multi-specialty group of 23 doctors in Midwestern city has opening for board certified or eligible specialists as follows: orthopedic surgeon, internist, pediatrician, otolaryngologist. All departments established and growing. Well-equipped clinic and excellent hospital facilities in community. Attractive financial plan leading to full partnership. Include curriculum vitae. Full expenses paid for applicants invited for interview. Write: MINNESOTA MEDICINE — 337; 496 Lowry Medical Arts Building, St. Paul 55102.

BUSY, GROWING aggressive 3-man partnership in Northwest Wisconsin serving a trade area of 15,000 needs a well-trained recent graduate with fulfilled military obligations to associate immediately on excellent salary, with partnership in 1 year if mutually agreeable. Modern 15 room air conditioned brick clinic building is being doubled in size this year. 32 bed hospital and new 42 bed nursing home one minute from clinic. New 1500 student consolidated school. Excellent hunting, fishing and outdoor sport facilities in immediate area. Contact: MINNESOTA MEDICINE — 317; 496 Lowry Medical Arts Building, St. Paul 55102.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE — 289; 496 Lowry Medical Arts Building; St. Paul, 55102.

WANTED: Generalist to associate with two man partnership in Northern Minnesota. Community has a thirty-seven bed hospital, X ray and laboratory technicians and nurse anesthetist. Good hunting and fishing. Adequate salary and time off. Contact: A. G. Janecky, M.D., Baudette Clinic, Baudette, Minnesota.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

WANTED: one or two general practitioners. Excellent clinic and hospital facilities. Rural practice established 18 years. Salary open, partnership if compatible. Lloyd H. Klefstad, M.D., Greenbush, Minnesota.

SACRED HEART, MINNESOTA, doctorless since 1961, wants general practitioner. Population 700, accredited hospital 10 miles away. Write: Rev. Robert Bardy, Phone 765-2547, Sacred Heart, Minnesota.

A THREE MAN group needs a fourth general practitioner in a fast-growing West St. Paul area. Begin with salary and join partnership with full participating advantages. Write: MINNESOTA MEDICINE — 326, 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTITIONER WANTED: to associate with physician-surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building three years old; with five large treatment rooms, lab.; x ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85-bed city hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D.; 920 South Cedar Street; Owatonna, Minnesota. Phone 451-4630.

LOCUM TENENS wanted for general practice in St. Paul from mid-February through March, 1966. Write: MINNESOTA MEDICINE — 328; 496 Lowry Medical Arts Building, St. Paul 55102.

MEDICAL ART. Drawings, charts and lettering for publication, slide lectures, movies, exhibits and television. Also three dimensional models. Al Hage — 339-1012, Minneapolis.

GENERAL PRACTITIONER AVAILABLE. Completing military June, 1966. Five years experience; married, desires group practice Rochester, Minneapolis, St. Paul or surrounding area, minimum OB and surgery. Write MINNESOTA MEDICINE — 331, 496 Lowry Medical Arts Building, St. Paul, Minnesota.

WANTED: young general practitioner to join six-man group consisting of 4 GPs, a general surgeon, and radiologist. College town of 5,500, 30 miles from Twin Cities. Also need LOCUM TENENS in general practice. Contact: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisc. Phone 425-5322.

WANTED locum tenens for month of February 1966. Can live in my home. If married, bring wife and children. Modern hospital and clinic, consultation available. Contact as soon as possible by mail or telephone: Wm. C. Heiam, M.D., Cook, Minnesota. Telephone: 666-3354 or 666-2261.

PHYSICIAN (General Medicine or Surgery) at 245-bed VA General Hospital in scenic Black Hills. Area offers excellent hunting, fishing, recreation. Requirements: Graduate approved school, citizenship, license any state, salary based on qualifications, housing available. Nondiscrimination in employment. Contact Chief of Staff, VA Center, Hot Springs, South Dakota 57747.

WANTED SOMEONE in East Side St. Paul general practice who would desire temporary locum tenens, one, two or three months. Write: MINNESOTA MEDICINE — 335, 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED: Generalist desiring fast start in too busy St. Paul practice. No covenants or contingent clauses. You move to available nearby independent office facilities as soon as you establish an adequate following of your own, or you stay as a partner if you desire. Incidentally lousy working conditions: new building, built-in Hi-fi, every third week off. If you desire to establish yourself permanently in present location. You name your own terms. Write MINNESOTA MEDICINE — 336, 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED: Immediate opening for young GP in an established medical corporation. Three man G.P. group located in rapid-growing North Suburban Metropolitan Area. 15 minutes from loop and large educational center. New clinic. New 150-bed hospital. Salary open, fringe benefits. Fridley Medical Center, P.A., 203 Mississippi Street, Minneapolis, Minnesota 560-2950.

FOR RENT: Successful medical building. Will help doctor or group of doctors get started in proven location in Northwest Suburban Minneapolis, 36th and Noble near two hospitals. Call or write Noble Drug, 4705 36th Avenue North, Minneapolis 22. Ju 8-9449.

WANTED — Internist, board certified or qualified, to associate with two board certified internists. Ten man multi-specialty group. (Lenont Peterson Clinic, Virginia, Minnesota) — Heart of the expanding taconite industry.

FOUR STAFF ADDITIONS to Southern California Group of 24 physicians. Internist with chest subspecialty, ophthalmologist, otolaryngologist, general practitioner. Partnership possibility after first year. Administrator, Gallatin Medical Group, 10720 S. Paramount Blvd., Downey, Calif.

WANTED: Young internist and pediatrician, board certified or eligible, to join 6-man group consisting of 4 GP's, a general surgeon, and a radiologist. College town of 5,500 only 30 miles from Twin Cities. Salary open with early partnership opportunity. Write or call collect: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisc., phone 425-5322.

EXCELLENT and immediate opening for one or two physicians. 17-bed fully-equipped municipal hospital with lab and x-ray facilities. Also private 40 bed nursing home. Complete clinic, including equipment, available for rent. Doctor owner retiring because of ill health. No investment needed. Prosperous agricultural community. Opportunity for rewarding lifetime practice. Phone 669-4421 collect, Clarkfield, Minnesota Hospital.

PSYCHIATRIC RESIDENCIES, positions available July 1966. Fully approved, balanced didactic and clinical experiences. Five-year career program: $8,895, $10,294, $12,048, $15,368, $16,203; NIMH general practitioner stipends $12,000 annually for three years in Michigan's water winter wonderland. Paul E. Kauffman, Ph.D., Director of Resident Training, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

WANTED: General practitioner able to do surgery. Present physician wanting to "semi-retire." Good community, prosperous farming. Good schools and churches. New hospital and clinic buildings. Contact: Warren Clinic, P.O. Box 107, Warren, Minnesota 56762.

WANTED: Young G.P. for rural practice partnership. No initial investment. Previous partner and well-equipped for dual practice. Good hospital — 12 miles and large medical center 30 miles on four lane highway. Small town in stable farming community, resort area, hunting and fishing, good school system. Contact: A. S. Midthune, M.D., Lake Park, Minnesota.

RELAXED, GRACIOUS COUNTRY LIVING viewing St. Croix River. Spacious, 3-bedroom, modern home on two acres — amidst stately shade trees. Recreation room. 17 miles to St. Paul. Write: Harlan Fisher, Route 5, Stillwater, Minnesota. Telephone 436-8844.

CHIEF OF PSYCHIATRIC SUPERVISORY STAFF needed to help with clinical supervision and teaching in expanding (18 Resident Physicians) fully-approved residence training program. Ideal living in active community in the heart of Michigan's Water-Winter Wonderland. Newly established position requires board certification in psychiatry and additional experience in clinical supervision. Salary range depending upon qualifications, $17,383 to $21,339 with liberal Michigan civil service benefits. Contact Arthur F. Dundon, M.D., Clinical Director, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

GENERALIST NEEDED. Death of associate in three-man group in general practice in White Bear Lake, Minnesota, requires immediate replacement. Salary with advancement to partnership negotiable. Excellent opportunity for young man in an established practice of young men (under 38 years old). New building in suburban area of St. Paul. Locum tenens also considered. Call or write: A. J. Rushay, M.D. or T. G. Briggs, M.D., 777-1341.

PHYSICAL MEDICINE AND REHABILITATION RESIDENCY — Approved 3-year program integrated with the University of Minnesota. Active service, 1,000 bed general hospital. Career residency salary $8,961-$12,510, non-career resident $4,325-$6,035 plus fringe benefits. Non-discrimination in employment. Contact PM&R Service, Veterans Administration Hospital, Minneapolis.

FREO, BY SAUNDERS SCHULTZ

FREE YOUR PATIENTS from
✓ deficient neutralization
✓ poor taste
✓ burdensome cost
with DICARBOSIL® antacid

■ **effective neutralizing power**—Two tablets in vitro[1], provide nearly 2 hours' relief within effective pH range 3 to 5.5.

■ **pleasant taste**—A fresh mint flavor patients continue to enjoy, because with Dicarbosil's unique* formulation, chalky aftertaste is no longer a problem.

■ **exceptional economy**—Due to its high neutralization capacity combined with low cost (1¢ or less per tablet), Dicarbosil is within the reach of all patients.

A Division of Lewis-Howe Company
319 South 4th Street • St. Louis, Missouri 63102

DEPROL®

meprobamate 400 mg. +
benactyzine hydrochloride 1 mg.

Indications: 'Deprol' is useful in the management of depression, both acute (reactive) and chronic. It is particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination. It is also useful for management of depression and associated anxiety accompanying or related to organic illnesses.

Contraindications: Benactyzine hydrochloride is contraindicated in glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use.

Precautions: *Meprobamate*—Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Side effects associated with recommended doses of 'Deprol' have been infrequent and usually easily controlled. These have included drowsiness and occasional dizziness, headache, infrequent skin rash, dryness of mouth, gastrointestinal symptoms, paresthesias, rare instances of syncope, and one case each of severe nervousness, loss of power of concentration, and withdrawal reaction (status epilepticus) after sudden discontinuation of excessive dosage.

Benactyzine hydrochloride—Benactyzine hydrochloride, particularly in high dosage, may produce dizziness, thought-blocking, a sense of depersonalization, aggravation of anxiety or disturbance of sleep patterns, and a subjective feeling of muscle relaxation, as well as anticholinergic effects such as blurred vision, dryness of mouth, or failure of visual accommodation. Other reported side effects have included gastric distress, allergic response, ataxia, and euphoria.

Meprobamate—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Dosage: Usual starting dose, one tablet three or four times daily. May be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended even though higher doses have been used by some clinicians to control depression and in chronic psychotic patients.

Supplied: Light-pink, scored tablets, each containing meprobamate 400 mg. and benactyzine hydrochloride 1 mg.
Before prescribing, consult package circular.

now...introducing a new high-strength dosage form

SIGNEM

A 'MAXIMUM SECURITY' ANTIBIOTIC*

* THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE
long established as the broad-spectrum agent of first choice in a wide variety of infections

* WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT
triacetyloleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline

* ESPECIALLY VALUABLE IN U.R.I.
provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered

* NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY
Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN® 375

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.

Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug.

Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

ANNOUNCING

THE TWENTY-NINTH ANNUAL MEETING
of
THE NEW ORLEANS GRADUATE MEDICAL ASSEMBLY

Conference Headquarters — Roosevelt Hotel

March 7, 8, 9, 10, 1966

GUEST SPEAKERS

Robert J. Rowe, M.D., Dallas, Tex.—*Colon and Rectal Surgery*
Walter C. Lobitz, Jr., M.D., Portland, Ore.—*Dermatology*
Bernard J. Haverback, M.D., Los Angeles, Calif.—*Gastroenterology*
Joseph J. Rupp, M.D., Philadelphia, Pa.—*General Practice*
Roy T. Parker, M.D., Durham, N. C.—*Gynecology*
Stefan S. Fajans, M.D., Ann Arbor, Mich.—*Internal Medicine*
John S. LaDue, M.D., New York, N. Y.—*Internal Medicine*
Joseph M. Foley, M.D., Cleveland, Ohio—*Neurology*
Duncan E. Reid, M.D., Boston, Mass.—*Obstetrics*
H. Saul Sugar, M.D., Detroit, Mich.—*Ophthalmology*
S. Benjamin Fowler, M.D., Nashville, Tenn.—*Orthopedic Surgery*
Walter P. Work, M.D., Ann Arbor, Mich.—*Otorhinolaryngology*
William O. Russell, M.D., Houston, Tex.—*Pathology*
William A. Silverman, M.D., New York, N. Y.—*Pediatrics*
C. Allen Good, M.D., Rochester, Minn.—*Radiology*
Louis M. Rousselot, M.D., New York, N. Y.—*Surgery*
Jerome A. Urban, M.D., New York, N. Y.—*Surgery*
Donald R. Smith, M.D., San Francisco, Calif.—*Urology*

Additional Speaker to be Announced

Lectures, symposia, clinicopathologic conferences, round-table luncheons, medical motion pictures, technical exhibits and entertainment for visiting wives. (All-inclusive registration fee—$25.00).

This program is acceptable for twenty-nine (29) accredited hours by the American Academy of General Practice.

The Clinical Tour AROUND THE WORLD visiting Hawaii, Tokyo, Nikko, Kyoto, Nara, Hong Kong, Bangkok, New Delhi, Agra, Jaipur, and Cairo. Leaving March 12 via air and returning April 12, 1966.

For information concerning the Assembly meeting and tour write Secretary, The New Orleans Graduate Medical Assembly, Room 1528, 1430 Tulane Avenue, New Orleans, Louisiana 70112.

---

a pertinent message from BENSON'S

What percentage of your patients deserve protective lenses?

10% 25% 50% or All of them?

A growing number of doctors apparently think protection should be a part of *every* prescription. And our records show that more than 50% of prescriptions are now processed in protective lenses.

Doctors with strong practices capitalize on opportunities to serve their patients better! And what better opportunity than to provide extra eye safety and to save patients the inconvenience and possible danger caused by lens breakage?

Build in protection with every prescription—specify BRx-Quality warranted HARDRx® or DURiKON® protective lenses.

your service-partners . . .

Physician's Diary

Life is to be fortified by many friendships. — To love and to be loved is the greatest happiness of existence. — Sydney Smith

NEW LOCATIONS: **Dr. L. Ashley Whitesell, Jr.** of Shakopee, has joined Drs. Catlin and Sandeen at the Buffalo Clinic . . . **Dr. Bernard Hanson** of Moorhead will practice in Bigfork . . . **Dr. Brandon Adams** has joined **Dr. D. H. Dewey** as an associate in Owatonna . . . **Dr. Dallas Glick** and **Dr. Alvin Wiens** have become associated in Mountain Lake.

* * *

New officers of the Minneapolis Ophthalmological Society are: **Joseph L. Garten, M.D.,** president and **Irving Shapiro, M.D.,** secretary.

* * *

Dr. Herb L. Huffington of Waterville has assumed the presidency of the Minnesota Academy of General Practice.

* * *

Dr. Karl W. Anderson of Excelsior, a member and treasurer of the Minnesota State Medical Association, was given the Harold S. Diehl award of the University of Minnesota Medical Alumni Association recently.

* * *

Dr. Hugh R. Butt, head of a section of medicine in the Mayo Clinic, was a visiting professor of medicine at the National Institute of Arthritis and Metabolic Diseases, Public Health Service, Bethesda, Maryland, November 15th, where he participated in medical rounds and seminars.

* * *

Roger P. Hallin, M.D. of Minneapolis has been named a director of the rehabilitation services of the Kenny Rehabilitation Institute.

* * *

Dr. Donald E. Stewart, Crookston, surgeon, has been elected president and board chairman of the Minnesota Division of the American Cancer Society.

* * *

Dr. Traz Akhavan, a native of Iran, has arrived in Alexandria to establish the Douglas County Diagnostic Laboratory.

Dr. Louis A. Brunsting, emeritus head of the Section of Dermatology of the Mayo Clinic, was reelected president of the American Board of Dermatology at its annual meeting.

* * *

Dr. Glen Gullickson, Jr. of Minneapolis was recently presented with "Golden Keys" by the American Congress of Physical Medicine and Rehabilitation. This is the highest honor the group confers.

* * *

The Minnesota Heart Association awarded grants to the following physicians: **Doctors Victor Lorber, Lewis Wannamaker** of St. Paul, **Dr. Earl H. Wood** of Rochester, and **Doctors Elia Ayoub, Ivan Frantz, Robert Good, Alfred Michael, Jr., Raymond D. A. Peterson and Joseph W. St. Geme, Jr.** of the University of Minnesota.

* * *

Dr. William L. Benedict, emeritus head of the Section of Ophthalmology; **Dr. Howard P. Rome,** senior consultant in psychiatry; and **Dr. James C. Cain** consultant in medicine, all of the Mayo Clinic, were named delegates to the White House Conference on Health held in Washington, D. C. in November.

* * *

The St. Paul Society of Psychiatry & Neurology was recently formed for the purpose of cultivating and improving the science and art of psychiatry and neurology in the greater St. Paul metropolitan area. There are presently twenty-five active members. Officers of the newly formed society are: **Dr. E. M. Hammes, Jr.,** president; **Dr. Robert Gumnit,** vice-president and **Dr. Glenn M. Lewis,** secretary.

* * *

The Interstate Clinic in Red Wing unofficially celebrated its 25th anniversary in September. The clinic opened with four doctors and three employees, and in the intervening years, has increased these figures to nine doctors and 30 employees.

* * *

Doctors Lynwood H. Smith, Ralph S. Zitnik, John W. Beabout, Edward J. O'Connell, Jorge E. Maldonado and John N. Simons have been appointed to the staff of the Mayo Clinic in Rochester.

Minnesota Medicine at a Glance

Aneurysmal Abscess — Huebl and Read Page 11

Although infection is an unusual cause of aneurysm, the intra-arterial administration of either angiographic media or, in addicts, concentrated paregoric mixtures have caused it in four cases. They involved the common carotid and femoral vessels and presented as pulsating abscesses.

Treatment was ligation of the involved vessel, incision, and wide drainage. One patient died subsequently of pneumonia and septicemia. The role played by extravasation, intramural injection, contamination, and chemical necrosis has been discussed, as well as the question of immediate or delayed reconstructive procedures.

Diagnostic Test for Coronary Disease — Cohen et al. Page 17

A new test for the detection of coronary artery disease is described. The procedure involves a coincidence counting method and the use of a positron emitter, rubidium^{84}. The coronary blood is measured by the logarithmic extrapolation of the myocardial clearances. Catheterization of the coronary sinus is not necessary; only a venous and an arterial puncture are performed. The data are objectively calculated by a digital computer.

Nitroglycerin increases the coronary blood flow in patients without coronary artery disease while failing to do so in individuals with coronary artery disease; this finding has become the basis for a diagnostic test in the recognition of coronary artery disease.

Pyoderma Gangrenosum — Altman and Mopper Page 22

Pyoderma gangrenosum is a rare, chronic, ulcerative skin disease beginning as a cutaneous abscess which rapidly breaks down to form large peripherally spreading ulcerations with a distinctive purple-red edematous and undermined border. It is frequently associated with chronic debilitating diseases, particularly ulcerative colitis.

The treatment is difficult: but the use of sulfone drugs, as illustrated in two cases, is effective in the long-term care of this condition. Sulfone drugs do not produce allergic cross reactions with sulfonimides and appear to be well tolerated in patients who are sensitive to sulfonimides.

Intracranial Hemorrhage — Chason et al. Page 27

Intracerebral hemorrhage accounts for approximately 200,000 deaths and it has been estimated that 2,000,000 people survive this cerebral vascular disease each year. In this study all individuals who die from this condition have suffered hypertension.

With the advent of relatively new procedures in the surgical correction of this disabling disease, the autopsy studies in this manuscript merely point out the urgency of pursuing more active treatment for patients who suffer from "stroke." It need not be a fatal or disabling disease.

The Carcinoid Syndrome — Circulatory and Cardiac Manifestations
— Zobl et al. Page 39

The carcinoid syndrome, ordinarily considered to be an invasive-type tumor, arising in the ileum with metastatic extension to the liver and heart, manifests its principal symptom by the production of an excessive amount of serotonin. In this instance, the symptoms consisted principally of facial flushing, sweating, weakness, abdominal cramps, and diarrhea.

In addition to the abnormally high serotonin levels, cardiac-catheterization studies revealed increased pulmonary artery pressure and abnormally high serum-histamine and catecholamine levels. It was suggested that these studies indicate that there are other basic, active substances in the circulating blood of patients suffering from the carcinoid syndrome.

Patch-Grafting — Thal et al. Page 45

There are occasions when a defect in the duodenum cannot be satisfactorily bridged and to close it without adequate patency has proven to be uniformly unsatisfactory.

Thal et al. have followed the procedure of applying an adjacent loop of serosa to fill in the defect which in effect then results in a shallow ulcer. This in turn rapidly heals as the ingrowing mucosa closes over the ulcer. The technique of this procedure is well illustrated in the manuscript.

Pulmonary Surgery for Emphysema — Hymes and Berkas Page 50

Patients with severe emphysema are excessive smokers who have pulmonary distress. In some instances when the cysts are large they are found to be tuberculous.

Without performing a pulmonary resection it is possible to give these patients considerable relief by removal of the cysts and obliteration of the pleural cavity. Poor pulmonary function is not a contraindication for surgery. Because giant air spaces are anatomically on the surface of the lung one need not remove the lobe or an extensive lung segment.

Cerebral Vasospasm — Thomas et al. Page 55

Though the concept of vasospasm as an etiologic factor in the production of cerebral disfunction, with intermittent attacks of paralysis, weakness, or dysphasia, has been recently disclaimed, the studies of Thomas et al. reveal that the topical application of certain drugs does produce vasoconstriction or vasodilatation. When given intravenously only papaverine produces vasodilatation.

Zinc Deficiency Syndrome — Prasad Page 59

A zinc-deficiency syndrome has been described for the first time and presents, in its clinical manifestations, a severe iron-deficiency anemia, hepatosplenomegaly, hypogonadism, dwarfism, and geophagia.

Metabolic studies indicate that the zinc content of the plasma, red blood cells, and hair was reduced, and that the excretion of zinc in the urine and stool was diminished.

Continued

When adequate diet and supplemental zinc were administered, the subjects under observation showed marked improvement: a marked increase in stature and a growth of external genitalia. Associated with this was an increase in the follicular stimulating hormone in the urine after the institution of treatment. It is obvious that in patients with iron-deficiency anemia one must also look for associated zinc deficiency.

Neonatal Gastric Rupture — Silbergleit and Berkas Page 67

Rupture of the stomach is the most common visceral perforation in the infant, occurring usually in the first few days of life. It is more common in premature infants, usually comes on suddenly, and is evidenced by a distended abdomen filled with air.

It has been thought that this condition is caused by peptic ulcer, distal obstruction, or trauma. Experimental studies on the dog indicate that distention of the stomach above 196 mm. of mercury will cause a stomach to rupture. It is speculated that the increased intra-abdominal pressure on the unborn child during the delivery could lead eventually to complete rupture of the gastric wall.

As soon as the diagnosis can be made surgery must be performed to close the defect.

Jaw Fractures — Monaco et al. Page 113

When an individual has a full complement of teeth and a jaw fracture, the problems are not as difficult as when an individual tooth is broken or when the jaw is edentulous.

The problem of treatment involves the restoration of the proper vertical-occlusal dimensions of the face. When this has been accomplished the results are usually very satisfactory. The technique of wiring a comminuted fracture is graphically illustrated.

Blind-End Ureter — Gonick Page 121

A man of 56 years had dull recurrent flank pain for 25 years, and his first investigative studies revealed pyuria with duplication of the right ureter and nonfunction of the left. These symptoms continued until he finally submitted himself for full evaluation and therapy. The persistent pyuria was finally identified as being due to a blind ureter on the left side, associated with a double ureter in the same kidney. After removal of the involved kidney he was relieved of his symptoms. It was concluded that this represented a combined neuromuscular defect which allowed urine to be refluxed into the blind ureter under the low pressure of a partly filled bladder, thus setting up the mechanism for chronic infection.

Complications of Anticoagulant Therapy — C P C Page 145

This represents the experience in one patient, in whom it appears that excessive anticoagulant therapy produced extensive bleeding in the epidural area of the cord, resulting in transverse myelitis.

Other complications of anticoagulant therapy are reviewed, and the lesson to be learned is that such therapy cannot be prescribed lightly without frequent clinical observations of the patient.

One of the most tragic cases reported in literature is the fatal hemorrhage in the nursing infant of a mother who was on anticoagulant therapy.

Traumatic Aortic Aneurysm — Berkas et al. Page 153

Traumatic aortic aneurysm may result from a major chest trauma, and if manifest as an acutely developed aneurysm the patient may present severe symptoms with evidence of blood loss. Dysphagia, dyspnoea, cough, and hoarseness are symptoms of a aneurysmal mass exerting pressure on the esophagus, bronchus, or recurrent laryngeal nerve.

Diagnosis is made on the basis of an extending mediastinal mass and can be confirmed by performing a retrograde aortogram. Operative repair can result in the salvage of a person who has a single correctable defect of this nature.

Basic Enzymology in Blood Clotting — Seegers Page 171

This is a masterful description of the basic enzymology in bloodclotting and can be thoroughly understood only by devoting conscientious moments to studying it.

The inability of many physicians to prepare a medical manuscript is a chronic, slowly developing disorder, which, unless treated relentlessly and vigorously, can progress to complete agraphia. Commonly called writer's syndrome, the disease is characterized by weakness, redundancy, indistinctness, triteness, endlessness, and rejection slips.

M. Therese Southgate, M.D.
Journal of the American Medical Association

Worry, according to a contemporary biochemist, "can be chemically defined as the psychic reaction of somatic saturation with paralytic acid and monosodic phosphate." — American Hebrew

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test[1-10] Reed[11] in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

Neo-Synephrine is a standard among topical vasoconstrictors. It is unsurpassed for reducing nasal turgescence in colds; and a most valuable aid in preventing and treating sinusitis.

Neo-Synephrine stops the boggy feeling of colds at once—works against factors that induce sinusitis. With Neo-Synephrine nose drops, spray or jelly, turbinates shrink on contact, obstructed ostia open and drainage is re-established.

In sinusitis, Neo-Synephrine helps to promote drainage and hasten recovery.* Used promptly, it helps clear the stagnant sinus and lessen the chances of chronicity.

Neo-Synephrine HCl is available in:
1/8% solution for infants
1/4% solution for children and adults
1/4% pediatric nasal spray for children
1/2% solution for adults
1/2% nasal spray for adults
1/2% jelly for children and adults
1% solution for adults (resistant cases)

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

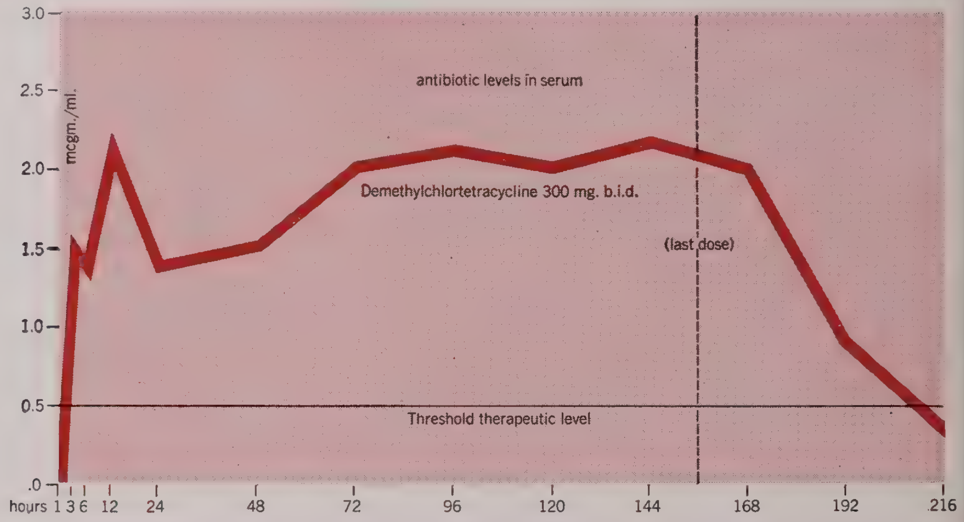
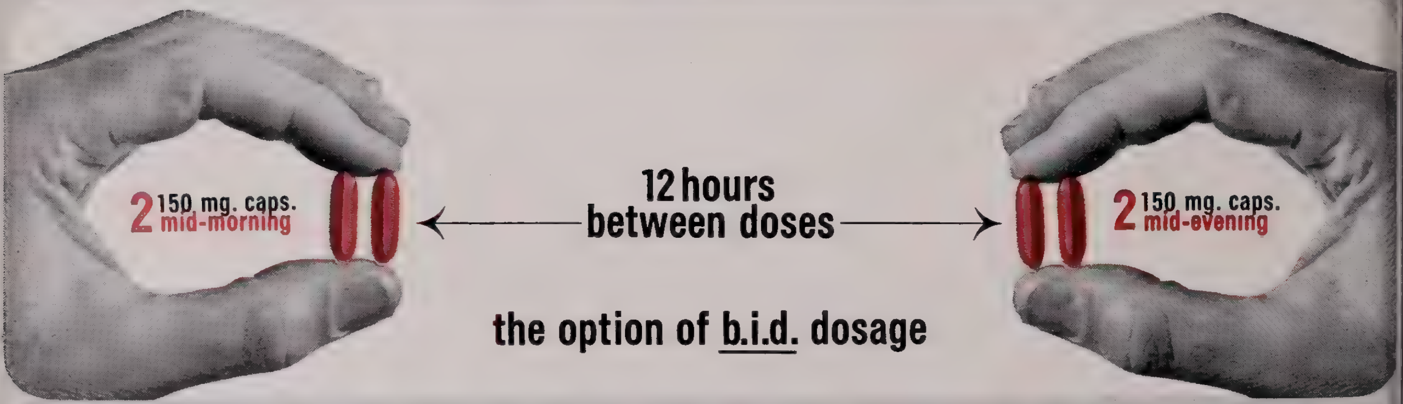
1-2 days "extra" activity

higher activity levels than other tetracyclines—with less peak-and-valley fluctuation



From Sweeney, W. M.; Dornbush, A. C., and Hardy, S. M.; Amer. J. Med. Sci. 243:296 (Mar.) 1962



12 hours between doses

the option of b.i.d. dosage

the "extra" benefits raise the level of antibiotic control

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE
150 mg. CAPSULES

Effective in a wide range of everyday infections—respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Side effects typical of tetracyclines include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis, dermatitis, overgrowth of nonsusceptible organisms, tooth discoloration (if given during tooth formation) and increased intracranial pressure (in young infants). Also, very rarely, anaphylactoid reaction. Reduce dosage in impaired renal function. Because of reactions to artificial or natural sunlight (even from short exposure and at low dosage), patient should be warned to avoid direct exposure. Stop drug immediately at the first sign of adverse reaction. It should not be taken with high calcium drugs or food; and should not be taken less than one hour before, or two hours after meals.

Capsules, 150 mg. and 75 mg. of demethylchlortetracycline HCl.
Average Adult Daily Dosage: 150 mg. q.i.d. or 300 mg. b.i.d.

LEDERLE LABORATORIES, A Division of AMERICAN CYANAMID COMPANY, Pearl River, New York
8035-9720 Lederle

President's Letter

Dr. James Z. Appel, the President of the American Medical Association, has recommended close and cooperative efforts by the physicians of the United States in working with those Government officials charged with implementing the Federal program of medical care.

This attitude, as could be expected, has been challenged by individual physicians and by some physician organizations. In reading Dr. Appel's reports both to the public and to various medical groups and associations, and in hearing Dr. Appel speak, the reasonableness of this recommendation becomes apparent. Provision of medical care for certain specified groups of Americans is now law, without constitutional challenge to date, and in consequence, must be obeyed. No law is ever implemented as it is written, however, and it is in the area of the development of regulations under which the law is enforced, that cooperative efforts can be a defense in the hands of those who are to be governed. It is in this area of the framework of developing regulations that sincere and dedicated physicians have been and are continuing to meet as technical advisory committees to administrators of the program.

Concession, in response to the demands of a law, may involve physicians in situations far from desirable, but is possible without compromise. To accept undesirable situations without strenuous efforts at improvement *is* compromise and should be wholeheartedly opposed by all physicians. That physician opposition to a legislative approach to the provision of medical care for self-sufficient Americans has been vigorous and vocal is now history. The later inclusion by law of those individuals originally recommended by the American Medical Association on the basis of medical indigency has in no way diminished medical opposition to care for those competent to care for themselves. Opposition to the law, however, should not be the present basis for criticism directed at those charged with the responsibility of best identifying what efforts, applied in what areas, will have the maximum results in providing, as physicians have always provided, optimum medical care under conditions physicians can modify, accept, and live with.

Our recent failure to convince our patients that the regimentation of physicians is in effect the regimentation of them as well, can never be the reasonable basis for any efforts at retaliation by obstruction or any other means. The integrity of our position can only be maintained by continuing efforts to support the rights of doctors as individuals and to develop new, and protect old, policies of benefit to patients, as individuals, as well.

To accept anything less *is* compromise. To continue the cooperative efforts Dr. Appel advises, and the American Medical Association is pursuing as a program developed and encouraged by the thoughtful deliberations of our elected physician-representation in the American Medical Association, is to serve medicine and our patients in the best medical tradition, in new and unusual circumstances.

Patients won't complain about bitter penicillin taste when you specify V-Cillin K. Here's why: It has a special coating, only one and a half *thousandths* of an inch thick. Because it is designed to dissolve after approximately six seconds, this barrier to bitterness remains on the tablet as it slides past the tongue. When the tablet reaches the stomach, however, the coating has dissolved, and the penicillin is ready for immediate absorption into the bloodstream.

Result? The proved efficacy of potassium penicillin V without the penalty of bitter taste.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

Demonstration of Tuberculosis in the Human Bone Marrow

Improved Technique

EMIL MARO SCHLEICHER, Ph.D.*
Minneapolis, Minnesota

"WE CANNOT afford to be satisfied with the present rate of progress against tuberculosis. The number of active cases reported each year is declining too slowly." This challenging remark cited by Tempel[1] and attributed to the Surgeon General, Luther L. Terry, U.S. Public Health Service, reveals clearly that tuberculosis is still a formidable disease.

That tuberculosis may be demonstrated by means of biopsy of the bone marrow organ has been amply demonstrated;[2-10] yet this helpful tool is not as widely employed as it should be. The reason for the lack of interest in this mode of case finding is the difficulties of evaluating the numerous marrow biopsy methods in use today and the greatly divergent results obtained by investigators.

It is the purpose of this communication to present an improved marrow-biopsy technique which, in our hands, is yielding uniform results. The technique is a modification of one previously reported;[3] the method is based on the knowledge that tubercles are within "marrow units" only.[2,3]

Marrow Units

The term "marrow units" is synonymous with marrow fragments, particles, and Markbröckel. They are minute masses of vital marrow tissue obtained by aspiration from the trabeculated areas of the bones.[11] Their consistency is jelly-like; thus they are very labile. Their color is light gray to red, and their diameter is 0.5 to 1 mm., with the larger ones predominating. In general they are lighter than the specific gravity of formol-saline fixing fluid, which is 1.010. Some eighty to one hundred fifty marrow units are contained in a 10-ml. sample when physiologic conditions prevail.

In disease the consistency, color, size, quantity, and specific gravity may be altered, as a result of changes in the functional state of the marrow organ, the cellular composition of individual marrow units, and modification of the trabecular framework in the spaces of which they are cast. Thus the size of the marrow units may be 0.1 to 4 mm., and few to more than a thousand may be present in a sample. All may be of the floating, heavy, or intermediate type, and again all three types may be present in a sample. These gross changes suggest that marrow units are anatomical entities.

Aspiration Sites

Sternum

The preferred site in the adult and young adult is the mid-line of the body of the sternum at the level of the second intercostal space (Figure 1).

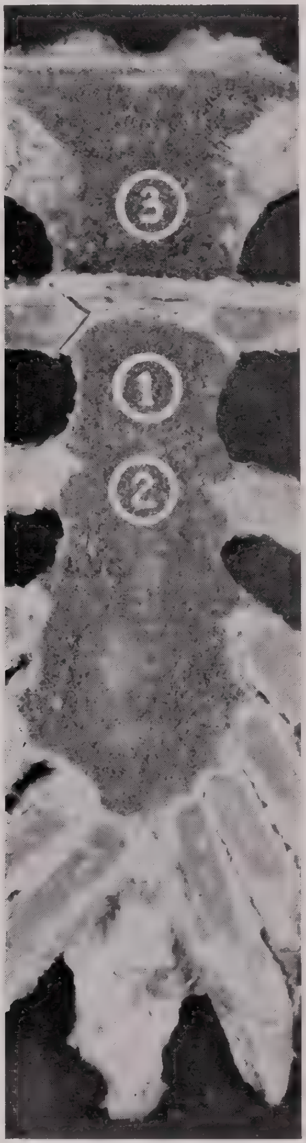

Fig. 1 — Longitudinal section of an average sternum of an adult. The preferred aspiration site is shown by the circle enclosing the number "1," the alternate areas by the circles "2" and "3."

The sternal area "2", manubrium area "3", anterior superior spine of the iliac crest, and spinous processes of the lumbar vertebrae are alternate sites, used only when multiple aspirations are necessary.

Manubrium

This bone is preferred as the aspiration site in children two to ten years of age.

Tibia

In children under the age of two years the preferred site is the tibia bone just below and slightly medial to the tibial tuberosity. The posterior iliac spine is the alternate site.

The reason for preferring the above cited bones for obtaining a marrow sample is based on studies of the distribution of functional marrow in these bones wherein Schleicher,[11] Denst and Mulligan,[12] and Hashimoto[13] have observed the presence of adequate amounts of red marrow. Hashimoto et al.[14] found a higher incidence of tuberculosis in the sternal-vertebral marrow than in other bones.

Aspiration Technique

When the aspiration instrument is properly situated in the medullary cavity, a 20-ml. sterile syringe is attached, its inside moistened with a sterile heparin solution (sodium heparin 1000 units, 1 ml., sterile physiologic sodium chloride solution, 9 ml.). The plunger is slowly withdrawn to the 2-ml. mark, and when marrow substance enters the barrel the plunger is rapidly pulled to the 20-ml. division and held there until 5 to 10 ml. of marrow substance is obtained. The specimen is immediately expelled into a paraffin coated glass vial and after the stopper is secured the vial is inverted several times to assure a uniform distribution of the heparin solution.

Standard Marrow Sample

It is routine in our institution to aspirate a marrow sample of 10 ml. from the adult and young adult patient, and 5 ml. from children. These amounts are not excessive considering that tuberculosis is not necessarily diffusely disseminated in the marrow organ, and that tubercles are within marrow units, with their quantity varying considerably in a random sample.

Processing of the Sample

Because of the physical character of the marrow units the sample must be immediately processed.* It is of the utmost importance that the separation of the marrow units from the blood and free fat part of the sample be carried out meticulously. To keep trauma and loss of marrow units at a minimum, a funnel valve assembly is employed (Figure 2). As the valve can be adjusted so that marrow units of 0.1 ml. are retained in the funnel, this mechanical aid is more efficient than the apparatus previously described.[15]

Method

1. The valve of the apparatus is adjusted to a filtration rate of 60 drops per minute of cold formol-saline fixing fluid (neutral formaldehyde, 10 ml., cold physiologic sodium chloride solution, 90 ml.) made up before use. The heparinized marrow sample is poured in the funnel, which is kept half filled with cold fixing fluid by continuous additions. The marrow units become exposed to clean fixing fluid while the blood and free fat part filter off and thus harden uniformly and rapidly. Marrow units sticking to the funnel wall or the valve stem are washed back into the fixing fluid.

2. When the fixing fluid is clear, the marrow units and the fluid are flushed into a glass beaker and allowed to harden at room temperature for one to two hours to assure complete fixation.

3. The sample is returned to the apparatus and the fixing fluid allowed to filter off.

4. Alcohol (80 per cent) is poured over the marrow units and the sample collected in a round or square glass dish with a grid. The marrow units may remain in the alcohol from one-half to one hour to overnight.

At this step the size range and quantity of the marrow units are determined. A plastic metric ruler is placed under the dish, or a few large and small marrow units are picked up with a medicine dropper and deposited on a metric scale and their size recorded. The marrow units are then tallied and the proportion of large to small is noted.

5. The alcohol is decanted and the marrow units exposed to alcohol (95 per cent) for one-half to one hour.

6. The alcohol is pipetted off and the marrow units exposed to two changes of acetone for one-half hour each.

7. The marrow units and acetone are transferred into a paper container (two

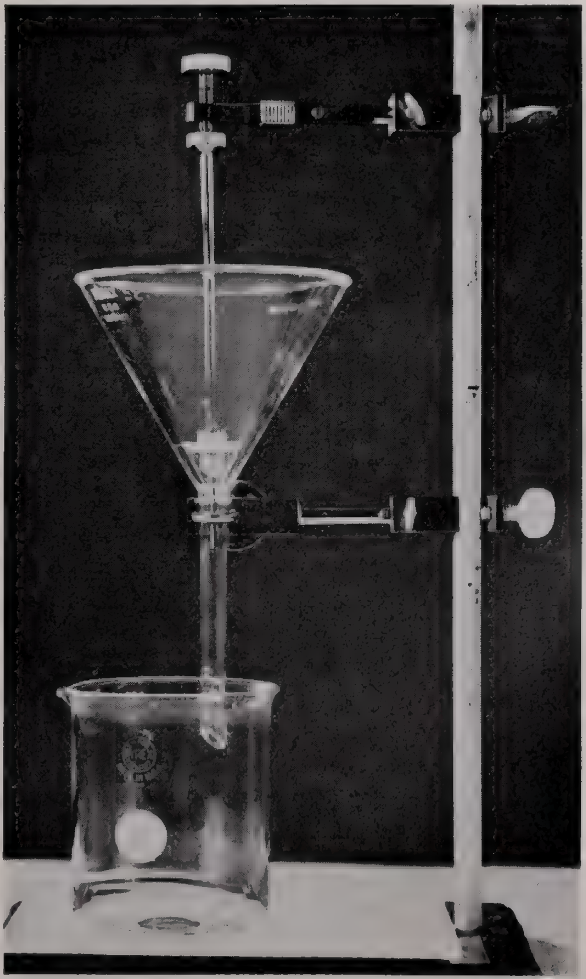

Fig. 2 — Funnel valve assembly** for the separation of marrow units from the admixture of blood and free fat part of the marrow sample.

---

*If a marrow sample cannot be processed immediately after removal the aspirate may be poured into cold formol-saline fixing fluid, the quantity of which should be ten times that of the sample. To assure proper fixation of the marrow units, the sample should be well dispersed in the fluid with a glass rod.

**Distributed by Aloe Scientific, St. Louis, Mo.

one-ounce No. 101 Dixie paper cups one inside the other) and the acetone pipetted off.

8. Melted paraffin (50-52°C.) is rapidly poured over the marrow units and well dispersed through the paraffin with a warm glass rod.

9. The sample is placed for one hour in an oven set at 58 to 60°C.

10. The paraffin is replaced by melted paraffin (56-58°C.) and the specimen returned to the oven for one-half to one hour.

11. The marrow units are then blocked in a square or rectangular tissue area. While blocking, care is taken to approximate the marrow units as closely as possible and in such a manner that the greater number lie on the same plane. Two or more blocks are made when the quantity of marrow units is very large. Serial sections are cut at 5 micra, mounted, and stained according to methods published elsewhere.[16,17]

Serial Sections

The number of serial sections to be prepared and examined is based on the diameter of the greater number of marrow units. Assume the latter is 1 mm., when serially cut at 5 micra, 200 sections are obtained. Since a single tubercle in general replaces one fourth to three fourths of the marrow unit parenchyma, and several tubercles are irregularly scattered through a marrow unit, 50 to 100 serial sections reveal the lesion.

Reliability of the Serial Section

The marrow sample from one of the patients on whom marrow biopsy was done for diagnosis contained 1580 marrow units with an average thickness of about 1 mm. Because of the large quantity of marrow units three blocks were made at the time of embedding. From each of these blocks 50 serial sections (250 micra) were cut. In only one of the three sets of serial sections was there a marrow unit with a tubercle, which appeared first in section 23, and the only two bacilli in section 25. The singularity of the tubercle was demonstrated by completely serial sectioning all three blocks, and the sparsity of bacilli by staining the sections showing part of the tubercle with the Ziehl-Neelsen method.

Figure 3 shows part of a serial section of the 1580 marrow unit aggregate and the single marrow unit harboring the tubercle. In contrast Figure 4 presents a heavily infected marrow from one of the patients with generalized miliary tuberculosis. The sample contained 34 marrow units, eleven of which harbored one to several tubercles. Acid-fast

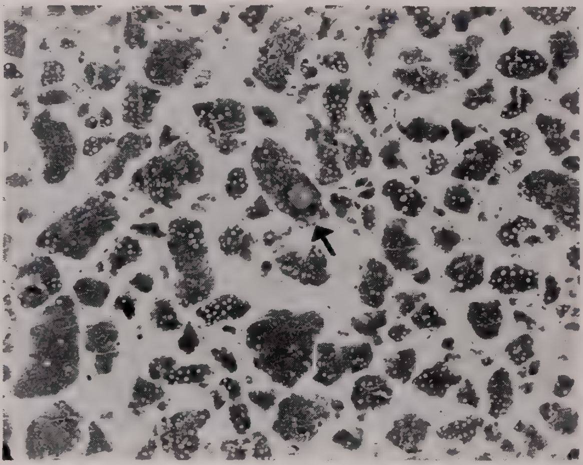

Fig. 3 — Part of a serial section of the 1580 marrow unit aggregate of one of the patients on whom marrow biopsy was done for diagnosis. Arrow points to the only marrow unit with a tubercle. Acid-fast bacilli could be demonstrated in only one section. Photomicrograph x 50. Hematoxylin-Eosin stain.

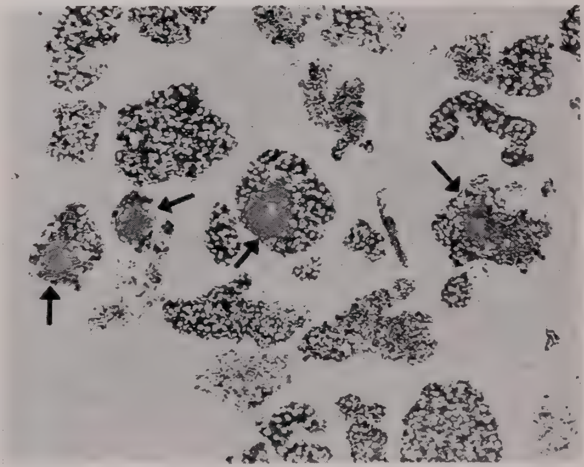

Fig. 4 — Part of a serial section of the 34 marrow unit aggregate of one of the patients with generalized miliary tuberculosis. Arrows point to marrow units with a tubercle. Eleven marrow units harbored tubercles but acid-fast bacilli were present in only seven tubercles. Photomicrograph x 125. Hematoxylin-Eosin stain.

bacilli were present in seven tubercles only, and in more than one serial section bacilli could be demonstrated. The tubercles first appeared in serial section 3.

Discussion

It is evident that for the demonstration of tubercles in the human bone marrow a biopsy technique is to be employed which yields uniform and reliable results. The technique must conform to the anatomy of the marrow organ in the trabeculated areas of the bones and allow obtaining a quantity of *marrow units* representative of the functional state of the organ. Emery and Gibbs[8] point out that "the probability of finding tubercles in the marrow will depend largely on the volume of tissue examined." They obtained a marrow sample of 0.1 ml. from forty-four children dying with generalized miliary tuberculosis, noting tubercles in thirteen specimens. These investigators saw tubercles only once in the routine single section made from the thirteen positive samples, thus pointing up the need of examining a large number of sections. Pease[6] procured a 2-ml. marrow specimen from each of fifty-six tuberculous patients, surveying 12 to 20 serial sections per slide, and found tubercles in nineteen samples. It is noteworthy that she saw tubercles in the marrow sample of four patients with miliary tuberculosis. Gormsen[5] aspirated 0.5 ml. and less of marrow from thirty-one patients with nonterminal tuberculosis mostly of the pulmonary type. He saw no tubercles in two to three sections made from the clot. Since marrow units tend to be scattered through the coagulum, failure to section the entire clot may leave infected ones in the uncut portion. Mooma and Alt[9] procured 1 ml. of marrow substance from eleven patients with far-advanced pulmonary tuberculosis. They used one half of the sample for histologic preparations. Moomaw and Alt expelled the sample on a glass plate transferring the marrow units with a dissecting needle to a filter paper. Trauma and loss of marrow units are inevitable. They examined eight sections from each marrow specimen noting tubercles in only one sample. The different results reflect clearly a direct relationship between the amount of marrow substance obtained and the mode of processing the sample.

Results with the Improved Technique

The results achieved with the marrow biopsy technique presented in this communication are shown in Table 1. Box I shows

TABLE I

Quantity and Frequency of Marrow Units with Tubercles Per Marrow Sample of Thirty-four Selected Patients with Known Tuberculosis, and of Seventeen Patients on Whom Marrow Biopsy was Done for Diagnosis

Diagnosis	Number of Patients	Marrow Pos.	Marrow Neg.	Amount Aspirated ml.	Range of Marrow Units Per Positive Sample	Range of Marrow Units with Tubercles	Range of Section Number when Tubercle First Seen	Positive Cases %
I Generalized Miliary Tuberculosis	17	17	—	5-10	34-253	11-27	3-8	100

Tuberculosis of meninges	1	1	—	10	147	7	48	
III Marrow biopsy for diagnosis	17*	6	11	10	80-1580	1-9	23-44	35.2

*Not previously reported

that in generalized miliary tuberculosis the marrow organ appears to be invariably affected. This is in accord with the findings of Chapman and Whorton,[18] and Hashimoto et al.,[14] who noted tubercles in all autopsy marrow specimens from patients with generalized miliary tuberculosis.

The data in Box II reveal a greater number of positive samples obtained from patients with other forms of tuberculosis than are reported by the above cited investigators.

Although the primary focus of the disease could not be established in the six positive cases out of the seventeen patients on whom marrow biopsy was done for diagnosis shown in Box III, the detection of tuberculosis in these individuals and concomitant demonstration of acid-fast bacilli in the tubercles are unequivocal proof of the value of bone marrow biopsy in case finding during life.

Conclusion

An improved marrow-biopsy technique for the demonstration of tuberculosis during life is presented. The technique is based on the knowledge that tubercles are within *marrow units*.

It is important that the admixture of blood and free fat be separated from the sample and that trauma and loss of *marrow units* be kept to a minimum. Table 1 shows that the incidence of tuberculosis of the human bone marrow is greater than has been noted by other investigators.

Acknowledgment

Thanks are extended to Dr. N. H. Lufkin, Director Department of Pathology and Clinical Laboratories, St. Barnabas Hospital, and his associates for the sustained interest in intravital marrow studies and support of this specialized research in the Hematology Section; to the medical staff for assigning patients to the study project; to Miss Patricia Taylor, medical technologist, for the meticulous processing of marrow units, and successful teaching of the laboratory part of the marrow-biopsy technique to individuals with various educational backgrounds.

Arteriovenous Fistula

Involving
the
Renal
Vessels

PAUL NAFFAH, M.D.*
HASSAN NAJAFI, M.D.**
RICHARD A. DEWALL, M.D.†
Chicago, Illinois

ARTERIOVENOUS FISTULA involving the renal vessels with an intact kidney is a rare entity. Of 34 such cases reported in the medical literature all but one occurred between the renal artery and the renal vein. The exception was a patient who, following an abdominal stab wound, developed a fistula between the aorta and the left renal vein. The case to be presented here will, therefore, be the second reported case of aorticorenal-vein communication with the fistula originating from the anterior wall of the aorta adjacent to the origin of the superior mesenteric artery. In spite of this critical location, the fistula was transected successfully with the preservation of a normally functioning left kidney. The rarity of the lesion, the technique utilized, and a review of the literature form the basis for this report.

Case Report

A 23-year-old male sustained a bullet wound of the abdomen on April 20, 1963, the bullet having

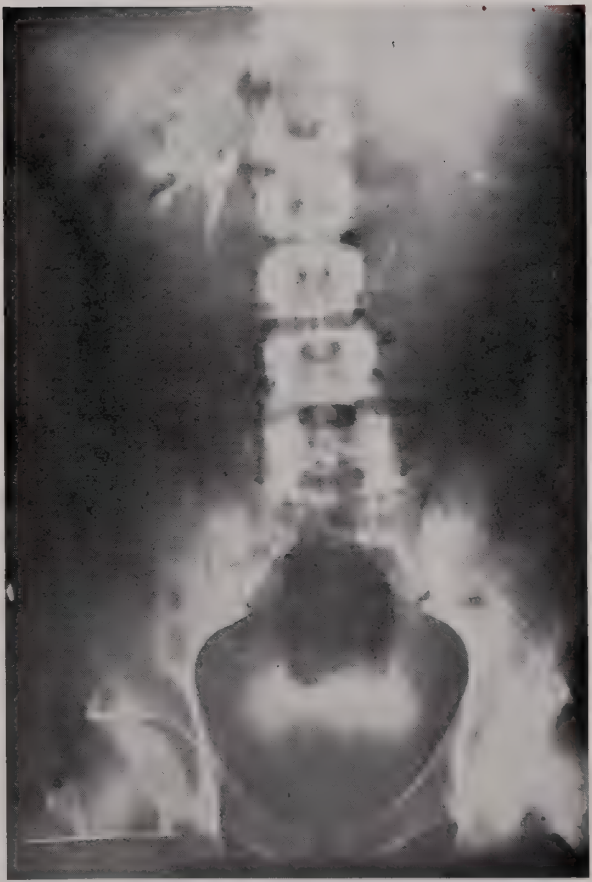

Fig. 1 — Failure of prompt excretion of the left kidney prior to surgery. In later film (L) kidney visualized better.

Department of Surgery.

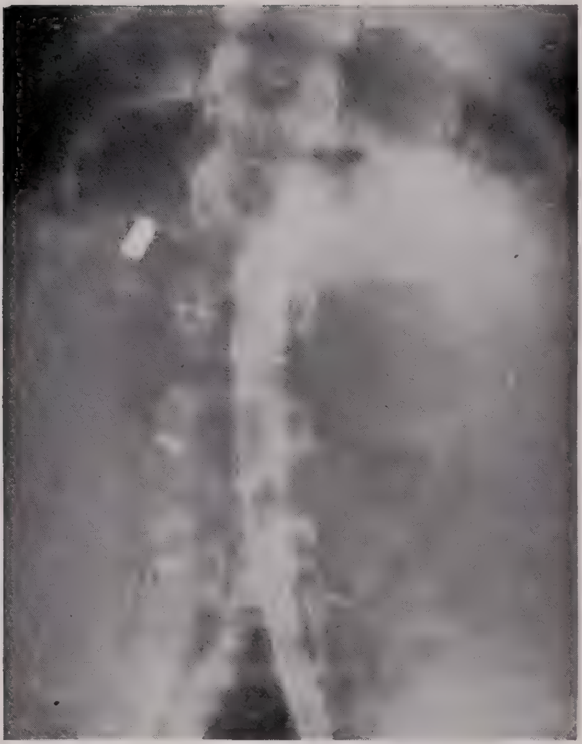

Fig. 2 — Aortogram showing opacified and distended left renal vein. Increased density overlying the aorta represents the site of the fistula.

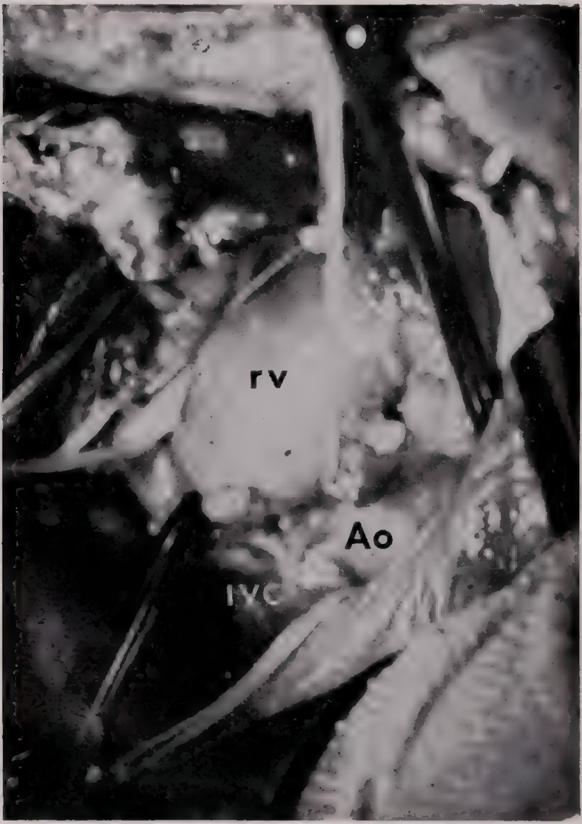

Fig. 3 — Markedly enlarged left renal vein (r. v.) Ao (Aorta). IVC (Inferior vena cava).

entered the left upper quadrant and lodged in the posterior abdominal wall. Immediate exploration revealed perforations in the stomach, pancreas, and the second portion of the duodenum, together with a large hematoma presumably from a lacerated lumbar artery. Two months after repair of these perforations he was readmitted with a diagnosis of partial intestinal obstruction which was treated conservatively.

Symptoms

His intermittent abdominal pain continued, however, and became further complicated by the appearance of a mass in the left upper quadrant of the abdomen. The size of the mass varied from time to time; but the mass itself never disappeared. On his third admission one year after the initial injury pertinent physical findings included a slightly tender, pulsatile mass, 8 centimeters in diameter, in the left upper quadrant. A continuous bruit was best heard in the mid back, but was also heard over the mass itself. His heart size was normal; his blood pressure was 130/60. Intravenous pyelogram showed delayed excretion of the dye from the left kidney (Fig. 1). A retrograde femoral arteriogram confirmed the presence of an arteriovenous fistula between the aorta and the left renal vein (Fig. 2). The left upper quadrant mass was felt to be unrelated to the fistula and was thought to be a pancreatic pseudocyst.

Findings at Operation

Surgery was performed on May 4, 1964. A large pseudocyst of the pancreas was found. In addition, an arteriovenous fistula was identified between the anterior wall of the aorta and the posterior wall of the left renal vein (Fig. 3). The left renal vein measured approximately 2 inches in diameter and demonstrated a continuous thrill which transmitted into the inferior vena cava. Complete dissection of the suspected area led to the localization of the fistula, which measured 1 cm. in external diameter and ½ cm. in length. It originated from the anterior wall of the abdominal aorta immediately adjacent to the origin of the superior mesenteric artery and terminated in the posterior aspect of the left renal vein (Fig. 4). Extensive retroperitoneal and periaortic fibrosis secondary to previous peritonitis and exploration contributed to difficulty in identifying the renal artery. Cord tapes were then placed around the aorta at the level of the diaphragm, the superior mesenteric artery, and the left renal vein on both sides of the fistula. The fistula was clamped at its origin by a partially occluding aortic clamp, while the left renal vein was clamped on both sides of the fistula, which was then transected. To avoid left renal congestion during venous occlusion, and without identification of the renal artery, the abdominal aorta was clamped at the level of the diaphragm. The defect in the vein measuring 1 cm. in diameter was closed using fine vascular suture. The proximal divided end of the fistula was then sutured and the partially occluding aortic clamp removed. The thrill disappeared and the left renal vein decreased markedly in size (Fig. 5). A drainage procedure was carried out for the pseudocyst of the pancreas. The patient had an uneventful recovery and left the hospital one week postoperatively. A postoperative intravenous pyelogram before discharge was normal (Fig. 6).

Discussion

The majority of the fistulae involving renal vessels have been described in the last decade, indicating a recent increasing awareness of this entity. The first case was reported by Varela in 1928.[41] Since then, at least 33 more cases have been added. The ages of the patients ranged between three and 70 years, there being no difference in sex distribution.

Etiology

As demonstrated in Table 1, of 34 cases with known etiology, 18 were considered to be congenital. These were usually multiple, arising from one or many branches of the renal artery. Pre-existing congenital aneurysms have been considered as the primary lesions in this group. The remaining cases were due to trauma, malignant infiltration, or infection. Penetrating wounds constituted the commonest cause in the traumatic group (nine cases). Two cases were recorded as due to surgical procedures. In all of the traumatic group the fistula was single and involved the main portion of the renal vessels, the majority the left renal vessels.

There were five fistulae due to malignant infiltration of the artery, which eroded into the vein establishing a communication. Two patients developed a fistula due to infection:

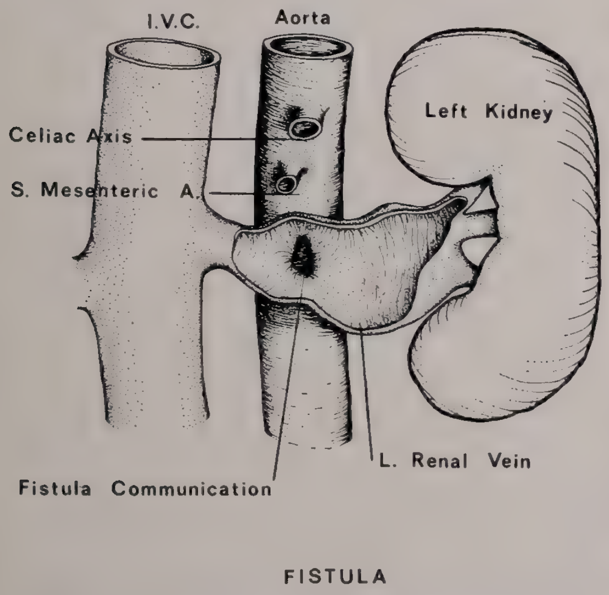

Fig. 4 — Diagram showing the location of the fistula and the dilated left renal vein.

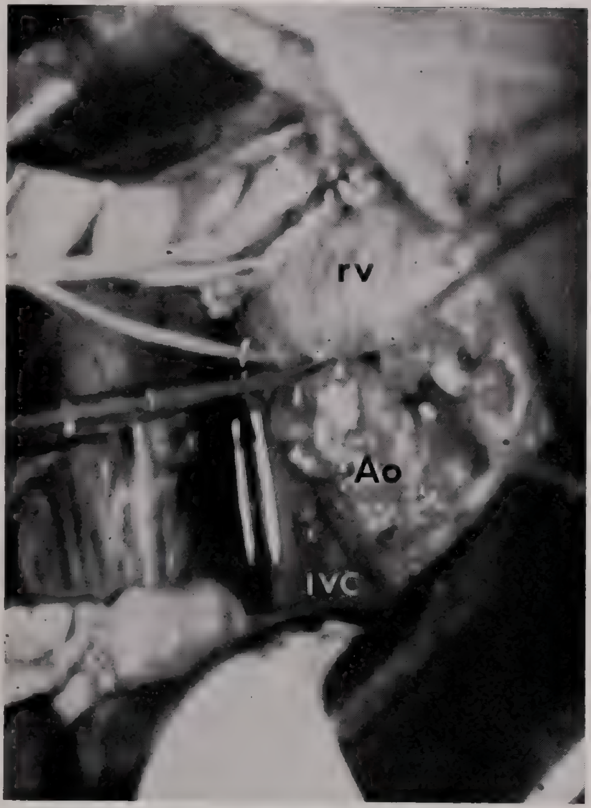

Fig. 5 — After clamping the fistula between the aorta and the renal vein, the latter decreased significantly in size (rv-renal vein). Ao (aorta) IVC (inferior vena cava).

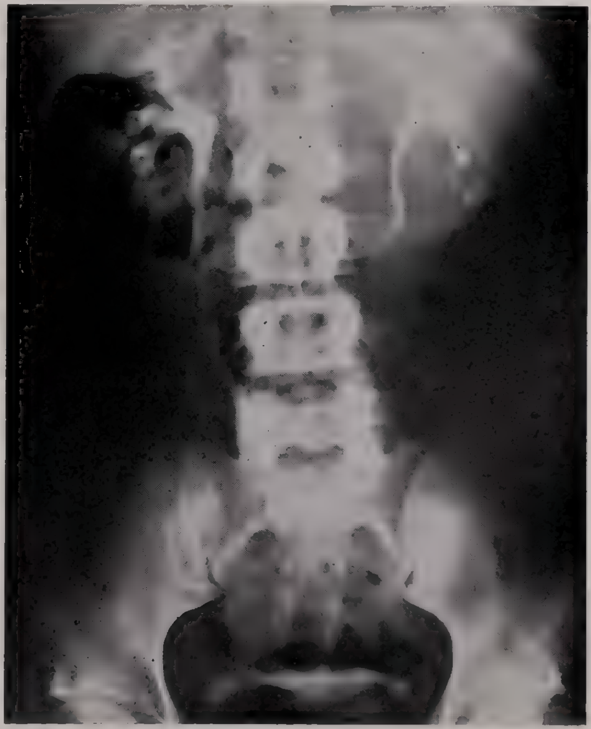

Fig. 6 — Simultaneous and equal excretion of the dye by both kidneys six days after closure of the fistula.

one secondary to subacute bacterial endocarditis, and the other due to an abscess formation.

C. Infection	2 cases

Clinical Symptoms

The presenting symptoms (Table 2) included fatigue, abdominal pain, palpable mass, flank pain with shock, peripheral edema, fever, and renal colic, with headache, dyspnea and hematuria constituting the most frequent original complaints. In general, most of the symptoms were those resulting from hypertension or congestive heart failure. Six patients experienced gross hematuria, in four of whom it was congenital. A continuous bruit in the flank was present in 24 cases. Evidence of congestive heart failure was reported in 20 cases regardless of the etiology. Hypertension ranked third in frequency (14 cases). Congestive heart failure was associated with hypertension in 10 cases. Wide pulse pressure was present in three cases, two with congestive heart failure. The remaining patients had normal blood pressure and complaints unrelated to the cardiovascular system, as in our case where the presenting symptoms were an abdominal mass in the left upper quadrant associated with pain.

Systemic and Local Effects

The effect of an arteriovenous fistula involving the renal vessels may be divided into two categories: systemic and local. The systemic effects are in general similar to those of peripheral arteriovenous fistula defined by Holman,[16,17] with the exception of the elevated blood pressure. The local effects on the tissues distal to the fistula are also similar. Epstein[11] summarizes the local renal effects as follows: decreased pulse pressure, ischemic changes, lowering of the renal plasma flow due to renal vasoconstriction, reduced glomerular filtration rate, and decreased chloride and water secretion. In the light of these observations it has been suggested that hypertension associated with arteriovenous fistula of the renal vessels may represent a Goldblatt phenomenon. However, experimentally created renal arteriovenous fistula in dogs, by Lasher and Glenn,[23] produced a mild and inconsistent hypertension. Regardless of the exact pathophysiology it is of special interest that of 19 cases of renal arteriovenous fistula associated with hypertension, 17 became normotensive following a nephrectomy.

Diagnosis

Clinical diagnosis of an arteriovenous fis-

tula based on the presence of a continuous bruit is confirmed by aortography. The classical picture is that of slightly opacified space overlying a well opacified, dilated and tortuous renal artery with early visualization of the inferior vena cava. Increased oxygen saturation of the renal vein blood obtained by means of a catheter introduced into the inferior vena cava is also diagnostic. The intravenous pyelogram shows some degree of abnormality from delayed to poor visualization or abnormal appearance of the calyces due to the compression by the sacular renal vein.

Treatment

Of the 34 cases reported, 32 underwent surgery (Table 3). Procedure consisted of nephrectomy in 29, heminephrectomy in two and transection of the fistula and preservation of the kidney in only one. Hypertension and congestive heart failure were relieved in 27 out of 29 patients. Two improved, but the blood pressure remained elevated; one showed no improvement, and one died. The ideal treatment is transection of the fistula with preservation of the kidney. Of the entire group in only one was this accomplished. It was achieved in the patient with a fistula between the aorta and the renal vein, similar to the case under discussion.

Summary

In a patient with traumatic arteriovenous fistula between the left renal vein and the aorta the fistula was successfully transected, and the kidney was preserved. A review of the literature disclosed 34 previously reported cases of renal arteriovenous fistula with only one aorticorenal vein fistula. Symptoms of congestive heart failure and hypertension were the leading complaints with hematuria being the common symptom in the congenital group. Hypertension has been related to the Goldblatt phenomenon.* Treatment has usually been nephrectomy with alleviation of hypertension in all but two cases. The involved kidney was preserved in only two instances. The exceptions were the patients with traumatic aorticorenal vein fistula.

Sulfonamide-Resistant

A. WALKER, M.D.**
R. L. STROM, M.D.†
Minneapolis, Minnesota

SULFONAMIDE-RESISTANT meningococci caused an outbreak of meningitis among recruits at the San Diego Naval Training Center in March, 1963.[1] Since that time, sulfonamide resistant Group B (Type II) Neisseria meningitidis has been observed with increasing frequency in both the military and civilian population. Eickhoff and Finland[2] reviewed the antibiotic sensitivity of meningococcal strains isolated from carriers and found only one isolate highly resistant to sulfadiazine.

During November of 1964, we studied meningococci isolated from the blood and spinal fluid of four children with cerebrospinal meningitis in the Bacteriology Laboratory at Hennepin County General Hospital. A Group C (Type IIa) strain of Neisseria meningitidis cultured from one of the patients was found to be highly resistant to sulfonamide drugs. The purpose of this communication is to alert the community to the existence of sulfonamide-resistant Group C meningococci in Minneapolis and to propose laboratory methods by which this problem may be studied.

Materials and Methods

The use of disc diffusion methods in evaluating micro-organism susceptibility to sulfonamides has been highly unsatisfactory. The reason is twofold. Many types of media contain peptones which inhibit the activity of the sulfonamides. In addition, the size of the zone of inhibition about a sulfonamide disc is inversely related to the number of organisms innoculated. Standardization of inoculum and use of Mueller-Hinton agar‡ partially compensate for these variables.

One solution to this problem is to use Mueller-Hinton agar plates with twofold dilutions of sulfonamide incorporated in the media. Plate dilution techniques, however, require vast numbers of plates with varying concentrations of antimicrobial agents and are laborious unless an inocula-replicating method is employed. Moreover, tests done on different media with different methods of plate innoculation cannot be directly compared.

A rapid and convenient quantitative tube dilution technique by which meningococcal susceptibility to sulfonamides may be compared is urgently needed. Wilson's[3] tube dilution technique, developed for study of beta hemolytic streptococci, appears to be adaptable to the evaluation of meningococcal sensitivities in our preliminary studies. Consider-

able experience with this method has been accrued at the University of Minnesota Hospitals while studying sulfonamide sensitivity of gram-negative isolates from genitourinary tract infections.

Bacterial isolates were maintained on sheep-blood agar and subcultured biweekly. Initial sensitivity testing was performed on Mueller-Hinton agar with discs containing sulfisoxazole .25 mg. (B.B.L.).

TABLE I
Case Material

Case	Presenting Symptoms	Laboratory Blood	Lumbar Puncture	Cultures	Sensitivities	Rx	Result
Case #1 D. S. (age 3 yr.)	Anorexia, lassitude, leg pains	WBC-51,000/MM^3 55% PMN	WBC-3460/MM^3 68% PMN Protein-228mg% Sugar-78mg% Smear-gram neg. diplococci	Throat, Blood and CSF-N. Meningitidis Group B (Type II)	Highly sensitive to sulfadiazine	Penicillin $12^6/M^2/10d$ Sulfisoxazole 150mg/kg/10d Chloromycetin 100mg/kg/2d	No residual
Case #2 C. B. (age 4 yr.)	Stiff neck, lethargy	WBC-23,400/MM^3 95% PMN	WBC-5100/MM^3 PMN-100% Protein-430mg% Smear-gram neg. diplococci	CSF-N. Meningitidis Group B (Type II)	Highly sensitive to sulfadiazine	Penicillin $12^6/M^2/10d$ Sulfisoxazole 150mg/kg/10d Chloromycetin 100mg/kg/2d	No residual

The tube dilution method used was a modification of that proposed by Wilson.[3] A working solution of sulfisoxazole diethanolamine containing 10 mg./ml. was made up from a stock solution with a concentration of 4 grams/10 ml. obtained from the hospital pharmacy. By means of sterile technique, 4.4 ml. of working solution containing 44 mg. of sulfisoxazole diethanolamine was added to a flask containing 37.0 ml. of S R Medium Base (Difco*). After 30 minutes in a 42 C. water bath, the flask was permitted to cool at room temperature. Horse serum, 3.0 ml., was then added to make a total of 44.4 ml. of solution. The final concentration of sulfisoxazole diethanolamine was 100 mg./100 ml. Thereafter, 18.5 ml. S. R. Medium Base was delivered into each of nine additional flasks; horse serum, 1.5 ml., was added to each to make a total of 20.0 ml. of solution. By transferring 20.0 ml. of the sulfisoxazole solution to a flask containing 20.0 ml. of growth medium, and continuing serial dilutions in this manner to the ninth flask, twofold dilutions ranging from 50.0 to 0.39 mg./100 ml. were obtained; the tenth flask served as a control medium. For actual testing, 2 ml. volumes of each dilution (nine tubes) and a growth control tube were used.

A heavy inoculum of Neisseria meningitidis was transferred from sheep-blood agar and grown in pure culture in tryptose-phosphate broth. After 24 to 48 hours, the growth in the broth was seeded into 20.0 ml. of S R diluent (Difco). Two strains failed to show adequate growth in tryptose-phosphate broth after 48 hours; however, an appropriate inoculum was obtained by substituting brain-heart-infusion broth as the growth medium. Representative pour plates were done to assure an adequate inoculum in all instances. Each of nine sulfisoxazole-containing tubes and the growth control tube were inoculated with the organism suspended in one drop of S R diluent. The highest dilution showing no turbidity was the minimal inhibitory concentration (M.I.C.) of sulfisoxazole for a particular organism. The reproducibility of this method has been extensively evaluated in routine sulfisoxazole tube dilution testing performed at the University of Minnesota Hospitals.

The plate dilution method utilized in our laboratory was performed by incorporating twofold dilutions of sodium sulfadiazine into Mueller-Hinton agar plates. A stock solution of sodium sulfadiazine containing 0.25 gm./ml. was obtained from the Hennepin County General Hospital pharmacy. A working solution of 25 mg./ml. was made up by adding 9.0 ml. of saline to 1.0 ml. of stock solution in a sterile test tube. Exactly 5.0 ml. of sterile saline was then delivered into each of nine additional test tubes. By transferring 5.0 ml. of sulfadiazine solution to each of the tubes in the series, twofold dilutions were obtained with a range of antibiotic concentration between 25.0 and 0.39 mg./ml. A volume of 0.1 ml. of each antibiotic concentration was then delivered into each of nine sterile petri dishes containing 9.9 ml. of Mueller-Hinton agar; the tenth petri dish containing only Mueller-Hinton agar was used as a growth control medium. In this study the range of antibiotic concentration in the Mueller-Hinton plates was from 25.0 to .39 mg./100 ml. The inoculum was taken from a Mueller-Hinton plate with a 3 mm. wire loop and hand streaked on the series of antibiotic containing plates. Adequate growth of each strain of Neisseria meningitidis was observed on the growth control media in each instance. The observed growth on each plate was graded qualitatively at 1 to 4+.

Sulfonamide blood level determinations were performed according to the method of Bratton and Marshall[4] and corrected for sulfisoxazole. The isolates were grouped by the tube agglutination technique performed at the Minnesota State Department of Health.

Case Reports

Neisseria meningitidis was isolated from the spinal fluid of four children with clinical meningitis. Brief summaries of the four case histories are presented below and in Table 1.

Case 1

A three-year-old Caucasian male was admitted to Hennepin County General Hospital on November 12, 1964, with a twenty-four hour history of fever, headache, nausea, and vomiting. He presented with a rectal temperature of 102 degrees F., photophobia, hyper-reflexia, and nuchal rigidity. Study of the peripheral blood revealed a white blood cell count of 55,000/mm^3. with 55% polvmorphonuclear leucocytes. A lumbar puncture showed a marked pleocytosis with a protein level of 228 mg%, and a sugar level of 78 mg%. The initial gram stain and subsequent cultures were positive for Group B (Type II) Neisseria meningitidis. The organism was sensitive to sulfisoxazole by the tube dilution technique and the plate dilution method at a level of 0.39%. The patient was successfully treated with penicillin and sulfisoxazole.

---

*Difco Laboratories, Detroit, Michigan.

Case 2

A four-year-old Caucasian female was admitted to Hennepin County General Hospital on November 30, 1964, with a two-day history of increasing lethargy, headache, and a stiff neck. She appeared semicomatose and had a rectal temperature of 102 degrees F., marked nuchal rigidity, generalized flaccidity, and a petechial rash extending over the trunk and extremities. The peripheral blood showed a white blood cell count of 23,000/mm.^{3} with a marked increase in neutrophils. A lumbar puncture disclosed milky fluid with a marked pleocytosis. The protein content was 430 mg%, and a gram stain was positive for gram-negative diplococci. The cerebrospinal fluid cultures grew out a Group B Type II Neisseria meningitidis, which exhibited marked sensitivity to sulfisoxazole at the 0.39 mg% level. The patient responded well to high doses of penicillin and sulfisoxazole.

Case 3

A six-month-old Caucasian male was admitted to Hennepin County General Hospital on November 10, 1964, with an eighteen-hour history of high fever and lethargy. En route to the hospital, the patient had a respiratory arrest and was admitted to the ward in a semicomatose state. Rectal temperature was 103 degrees F. Nuchal rigidity, papilledema, and a diffuse petechial skin rash were present. A white blood cell count was 14,500/mm.^{3} with 55% neutrophils. The initial lumbar puncture revealed a prominent pleocytosis. The spinal-fluid protein level was elevated to 234 mg%, and the sugar level decreased to 9 mg%. The gram smear showed large numbers of gram-negative diplococci. Cultures of the nasopharynx, spinal fluid, blood and petechiae grew out Group C Type IIA Neisseria meningitidis, which proved to be highly resistant to sulfisoxazole by the tube dilution and the plate dilution technique (Tables 2 and 3). The patient recovered slowly after a fourteen-day period of therapy with high doses of penicillin and sulfisoxazole. The father of this patient, a career army enlisted man, had been transferred to Minneapolis in October, 1964. On tracing his whereabouts during the preceding year, no exposure to epidemics of sulfonamide-resistant meningococcal disease could be demonstrated.

Case 4

A three-year-old Caucasian female was admitted to Hennepin County General Hospital on November 20, 1964, after two days of high fever and lethargy. On admission, a generalized petechial rash was apparent and the child was convulsing and semicomatose. Marked nuchal rigidity and papilledema were evident. After a respiratory arrest, she was placed on positive pressure respiration. Over the next two days her condition deteriorated and she expired. The initial white blood cell count was elevated to 24,300/mm^3. A lumbar puncture showed large numbers of gram-negative diplococci. The cloudy cerebrospinal fluid showed a striking pleocytosis with a protein level of 340 mg% and a sugar level of 15 mg%. The peripheral blood and spinal fluid cultures grew out Group B Type II Neisseria meningitidis with marked sensitivity to sulfisoxazole by the tube dilution and plate dilution methods. Autopsy findings confirmed the clinical impression of marked cerebral edema and meningeal inflammation.

Results

Sensitivity testing was done for both sulfadiazine and sulfisoxazole. The sulfadiazine sensitivity determinations by the Mueller-Hinton agar plate dilution method are presented in Table 2. Note that the Group C (Type IIa) meningococcus isolated from Case 3 shows significant resistance to sulfa-

diazine. The Group B (Type II) meningococci isolated from Cases 1, 2, and 4 uniformly show marked sensitivity to sulfadiazine. The four cerebrospinal fluid isolates were also tested for sensitivity to sulfisoxazole by the modified Wilson Tube Dilution Method. Table 3 shows that the Group C (Type IIa) isolate from Case 3 was resistant to 25 mg./100 ml. of sulfisoxazole, whereas the remaining Group B (Type II) isolates exhibited marked sensitivity. No significant difference was observed in parallel determinations with sulfadiazine and sulfisoxizole.

Group B (Type II) Neisseria meningitidis have been implicated in all previous epidemics caused by sulfonamide-resistant organisms. Thus far, no sulfonamide-resistant Group C (Type IIa) strains of Neisseria meningitidis have been reported from cases of clinical meningitis. It appears that the spectrum of resistant organisms is increasing to involve additional strains of meningococci.

Discussion

The treatment of meningococcal carriers with sulfadiazine was standardized in the classic studies of Schoenback and Phaer[5] in 1948. Recent military experience suggests that neither sulfadiazine nor penicillin G when given orally for a four-day period is effective in eradicating the carrier state.[1] The occurrence of fatal cases of meningococcal meningitis in this community requires us to re-evaluate our program of prophylaxis in meningococcal carriers. The efficacy of penicillin G in high dosage in eliminating the carrier state remains to be defined. There appears to be little doubt that penicillin G is an excellent adjunct to sulfadiazine in the treatment of active clinical cases of meningitis. In our studies, the resistant Group C (Type IIa) strain as well as the Group B isolates were highly sensitive to penicillin G. A satisfactory therapeutic effect was obtained by treating our patients with penicillin G and sulfisoxazole.

Summary

Bacterial isolates from four cases of meningococcal meningitis treated at Hennepin County General Hospital have been studied for resistance to sulfonamide drugs, and it was found that Group C (Type IIa) strain of Neisseria meningitidis, isolated from the blood and spinal fluid of one child, was highly resistant to sulfonamide. A modified Wilson Tube Dilution technique has been found to be an effective means of determining sensitivity to sulfisoxazole.

Pliny on Birth Control

Pliny declared against abortive drugs as well as love charms, but cited one recipe for birth-control for the benefit of over-fecund women, consisting of a ligature of two little worms found in the body of a certain species of spider and bound on in deer-skin before sunrise. After a year the virtue of this charm expires.*

Conventional Scanning vs. Scintillation Camera

A Comparison for Evaluation of Brain Pathology

MERLE K. LOKEN, Ph.D., M.D.*
GERALD TELANDER, M.D.*
STEFAN LAXDAL, M.D.*
Minneapolis, Minnesota

A DETAILED comparison of results of organ visualization by conventional scanning to those obtained with the scintillation camera[1] is under way. This study includes all organs which may be visualized using selected radioisotopic preparations. Special attention is being given to short-lived radioactive materials which will permit improved resolution and decreased radiation exposure to patients despite administration of relatively larger amounts of these materials than are normally employed for conventional scanning. This is a preliminary report of studies performed with mice, a brain phantom, and of patients suspected of having brain tumors. Special consideration has been given to the use of 99m technetium in the form of pertechnetate[2] as an agent for brain studies, and comparison is made to results obtained with 197 mercury chlormerodrin. When possible, both agents are being used for camera and scan studies in individual patients.

Technical Considerations

99m technetium is obtained from a 99Mo-Tc generator.** These generators are now prepared so that the 99m technetium may be eluted by addition of pyrogen-free normal saline to the resin column. We find that more than 90 per cent of the technetium is removed in the first 10 milliliters of eluate with each daily milking. Yields of the technetium are within expected values (about 75 per cent of that calculated) with less than 0.1 per cent 99 molybdenum contamination. Daily samples have been assayed using both the 400-channel analyzer and liquid scintillation systems. Both methods show the expected decay constants for 99m-Tc and 99Mo. The energy spectrum as visualized from the analyzer unit is likewise as expected. Following sterilization by autoclave, the 99m-Tc is standardized by comparison to a known activity of 57-Cobalt.[3]

Experiments in which mice were given

**Brookhaven National Laboratories, Upton, New York and Nuclear Consultants Corporation, St. Louis, Missouri.

100 microcuries of technetium by intravenous route and sacrificed at various times thereafter have shown that the 99m-Tc is initially handled very much like radioactive iodine. At one hour after administration the majority of the 99m-Tc removed from the blood stream is found in the salivary glands, thyroid, and stomach. The 99m-Tc concentration in these organs gradually increases for about 2.5 hours, after which time there is a gradual clearance, so that less than 10 per cent of the maximum radioactivity remains after about 10 hours. The uptake of the 99m-Tc by other organs such as the liver, spleen, pancreas, kidney, and brain reaches a maximum at about one hour, at which time the activity in all organs is less than 10 per cent of that seen in the salivary gland on a per gram basis. These data together with 99m-Tc clearance measurements in patients indicate that the radiation exposure to patients is quite low despite the use of 10 millicuries for an adult patient (Table 1).

The value of conventional scanning in the diagnosis of disease in various body organs is well established.[5] The scintillation camera, on the other hand, is a new instrument designed for comparable studies but not yet fully evaluated. This unit has no moving parts as does a scanner and functions in a manner quite analogous to an x-ray fluoroscope. Thus the entire field of view (11 inches in diameter) is presented to the read-out device (Cathode ray tube) which is viewed by a polaroid camera. A variety of control settings have been tried with the scintillation camera. It is found that a window setting of 20 (0.2 of the widest window obtainable) appears to give optimal results (i.e., the best counting rate with a minimal loss in resolution). This represents a window which is approximately 20 per cent of the gamma photon energy being analyzed. A count-rate meter facilitates voltage adjustments for optimal count rate for the selected window setting. The optimum threshold setting for this device appears to be 5.5 volts. With our scanner, conventional technique has been used for 197-Hg. scans, whereas maximum speed obtainable (60 cm. per minute) has been used for all 99m-Tc scans.[4]

The 11-inch diameter crystal of the scintillation camera is adequate in size for most studies. There are situations (visualization of lungs or hepatomegaly) in which a larger field of view would be desirable. The collimating system appears to be the factor which limits the resolution obtainable with our model of the scintillation camera. This is most apparent for the lower energy gamma emitters. A thinner lead collimator than is currently available with a greater number of holes and thinner septa would probably improve sensitivity and also permit better resolution for use with radioisotopes such as 197-Hg.

Results

Phantom studies performed with 99m technetium with both camera and scanner indicate that comparable resolution is obtainable with either unit if there is adequate control of technical factors. "Tumors" of various sizes, concentrations, and locations have been studied. It is found that approximately 200,000 total counts should be accepted in the scintillation camera to obtain about comparable resolution using our technique for scanning (four scanning lines per centimeter) using a Picker Magnascanner

TABLE 1
Radiation Dosage for Brain-scanning Agents

Isotope	Amount Used	Total Body Dose (Rad)	Target Organ (s) Dose (Rad)	
99m-Tc	10mCi	0.1-0.2	0.5-1.0	Stomach & Salivary Glands
			1.0-1.5	Thyroid
			1.5-2.5	Large Bowel
197-Hg.	10μCi/Kg.	0.02	3-12	Kidney
203-Hg.	10μCi/Kg.	0.18	30-120	Kidney
I^{131}HSA	5μCi/Kg.	0.4	0.4	Blood, Thyroid

with a 3-inch diameter crystal. It is possible to demonstrate laterally placed "tumors" of 2.5, 5.0, and 10.0 cc. volume provided the radioactive concentration is at least seven, four and two times greater, respectively, than the concentration of surrounding brain-tissue equivalent material. Pseudo-tumors placed more medially in the phantom require relatively greater concentration differences for visualization. Comparable studies performed with our camera and scanner using 197-Hg. in the phantom have yielded similar results. It is our impression that slightly better "tumor" delineation is possible with 99m-Tc, particularly for those located near the mid-line, although further study of the factors used with these instruments is necessary to prove this point.

For brain studies we normally obtain four views of the head; because of the camera maneuverability we are able to do these studies in one of several patient positions. The position is usually selected on the basis of the comfort of the patient. For studies with 99m-Tc we give six to 10 millicuries intravenously. In our experience, the optimum time for camera pictures and scans appears to be about two hours after administration of the isotope. The count rates obtained with the camera vary from 150,000 to 350,000 cpm using 99m-Tc. We feel that at least 200,000 total counts and preferably 500,000 should be obtained for the best results. For studies using radioactive 197-Hg. chlormerodrin, we use one millicurie of isotope for the average adult patient. This is administered intravenously and the camera pictures and scans made three to four hours later. We find that 100,000 total counts per projection are usually sufficient for a good camera study with 197-Hg. More total counts would be desirable, but count rates of about 15,000 cpm limit the time available per projection.

*Studied with both scanner and camera

More than 200 brain studies have been performed to date using the scintillation camera. The majority of these patients were also scanned with our Picker Magnascanner for purposes of comparison. To date we have found that almost all brain lesions visualized using one of these units may also be demonstrated by the other. In one study of a patient with a brain abscess, the lesion was visualized more clearly on the camera picture than it was on the scan. Results of our patient studies are shown in Tables 2 and 3.

Included are reproductions of scintillation camera pictures and conventional scans on two of our patients. 197-Hg. chlormerodrin was used in one patient study and 99m-Tc in the other.

Case 1

This three-year-old boy was seen by a private physician when his parents noticed proptosis of the left eye and increasing irritability. Signs of increased intracranial pressure were found during physical examination. Surgery was performed in October, 1963, with discovery and incomplete removal of a left optic glioma invading the frontal lobe. The patient did well postoperatively until March, 1965, when increased irritability and increased intracranial pressure were again noted. A brain study was done following intravenous administration of 200 microcuries of 197-Hg. The accompanying photographs (Figure 1) demonstrate the lesion that was seen with the scintillation camera and a conventional scan. Surgery was performed and a large recurrent tumor was found in the area shown.

Case 2

This 26-year-old male was seen in July, 1964, complaining of persistent headache and increasing lethargy. A brain scan was performed using 600 microcuries of 197-Hg. and showed increased activity in the left parietal area. Angiography also indicated a space-occupying lesion in the same position. At surgery a grade III astrocytoma of the left parietal lobe was removed. This patient did well until April, 1965, when headaches recurred along with bulging of the bone flap in the area of the initial surgery. A study performed at that time with 99m-Tc and the scintillation camera showed recurrence of the tumor (Figure 2).

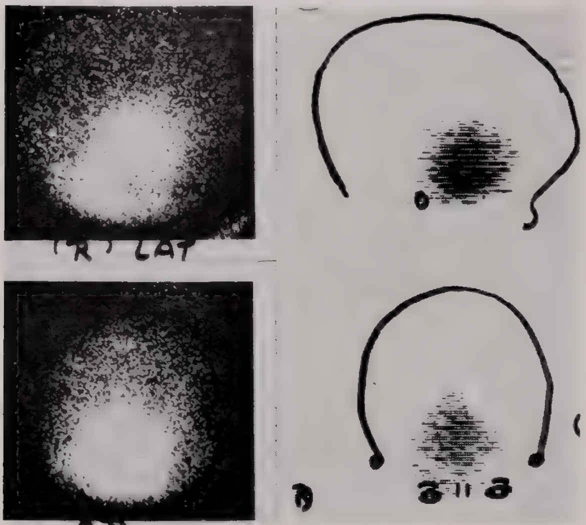

Fig. 1 — Anterior posterior and right lateral skull projections of a 3-year-old boy with recurrent optic glioma. The pictures on the left were taken with the scintillation camera and those on the right were done using the conventional magnascanner. 197-Hg. chlormerodrin was used for this study.

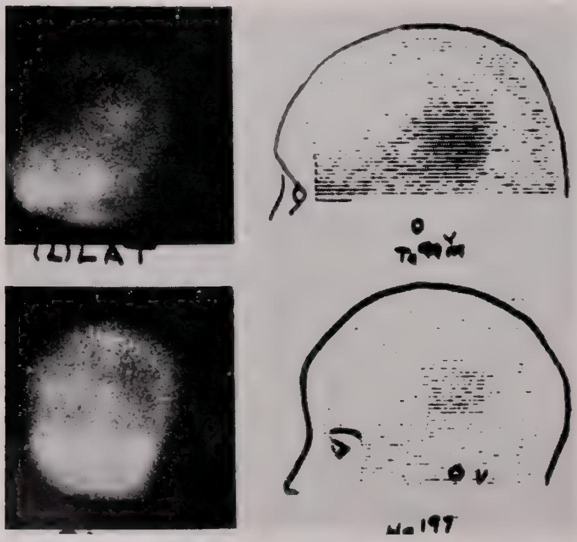

Fig. 2 — Posterior anterior and left lateral skull projections of a 26-year-old man with a left parietal lobe astrocytoma. The two pictures on the left were obtained with the scintillation camera of the PA (lower left) and left lateral positions (upper left). The two scans on the right were left lateral projections of the same patient using 99m-Tc (upper right) and 197-Hg. (lower right).

Discussion

A conventional scanner and a scintillation camera are being used to evaluate brain pathology in patients who have received either 99m-Tc pertechnetate or 197-Hg. chlormerodrin by intravenous route. The scintillation camera is a relatively new device and 99m-Tc is a recent addition to our armamentarium of radioisotopes. Thus evaluation of techniques and radioisotopic agents has been undertaken.

By virtue of its design the scintillation camera is of greatest potential value when used to study organs containing a relatively large amount of radioactivity. This combination permits data to be accumulated in a short period of time so that multiple projections of the organ and/or time-lapse studies of the clearance of radioactivity from the organ may be undertaken.

The use of large amounts of radioactive materials in patients is frequently contraindicated because of radiation hazards involved. This problem may be eliminated, at least in part, by using very short-lived radioactive materials such as 99m-Tc (Table 1). Its short physical half-life of six hours and its emission of a single gamma photon of 140 Kev. gives it nearly ideal physical properties for use with the scintillation camera. It is also being used with conventional scanners, but to some degree its value is compromised because of the finite speed obtainable with the scanning units.

Results of phantom studies indicate that foci of 99m-Tc or 197-Hg. in pseudotumors may be demonstrated as readily with the scintillation camera as with a scanner. Likewise brain pathologies (primary neoplasms, metastases, subdural hematomas and brain infarction) appear as well visualized with 99m-Tc pertechnetate as with 197-Hg. chlormerodrin which has been the principle agent for brain-tumor diagnosis for the past several years (Tables 2 and 3).

We are depending more and more upon 99m-Tc and the scintillation camera for study of patients suspected of having brain pathology. Advantages of the camera include the shorter time per projection (two to four minutes as compared with 15 to 30 minutes for a conventional scan) and the ease of positioning the camera for various patient views. Thus patients may assume reasonably comfortable positions during studies and are not required to remain immobile for nearly as long periods of time as are required for scans. Furthermore, more patients may then be studied during the working day, which is an important factor for a busy clinic.

We have found that the small polaroid picture obtained with the scintillation camera is somewhat more difficult for us to interpret than is the life size scan. This is partially due to our limited experience with the camera as compared to a much greater experience with conventional scanning. By making slides of the camera pictures and projecting these on a screen, we find that interpretations are easier to make.

IT'S THE LAW

Doctor's Opinion Based on Misinformation Shall Be Disregarded

An orthopedic surgeon's opinion that the back condition of a claimant for workmen's compensation benefits could conceivably have been caused by an injury received in an industrial accident must be disregarded, since it was based on an incorrect medical history given him by the claimant, a Louisiana intermediate appellate court ruled.

The claimant was injured when a grinding stone he was using broke apart and part of it struck him in the abdomen. He was treated by his employer's doctor.

Fifteen months later, the claimant consulted the orthopedic surgeon because he was suffering from low back pain. The claimant told him that X-rays were taken, at the time of the accident, in a position similar to that used by the orthopedic surgeon in X-raying his lower back and told him that he had been given crutches the next day. The orthopedic surgeon concluded from that information that the claimant's present disabling back condition could conceivably have been caused by the accident.

The employer's doctor testified that no X-rays were taken of the claimant in connection with the treatment of his injury. The crutches were given to him merely because he complained of back pain which the doctor could not relate to the claimant's injury.

Since the orthopedic surgeon's conclusion was based on incorrect factual premises, it must be disregarded; and it could not be said that the accident even "conceivably" could have caused the claimant's present back condition.

Primary Lymphosarcoma*

PAPAIOANNOU[1] SUMMARIZED primary lymphomas of the lung recording a total of 93 cases. Seventy-seven of these were classified as a type of lymphosarcoma, 16 as reticulum cell sarcomas. There was no localized Hodgkin's disease of the lung. Thirty per cent of the 93 patients had asymptomatic nodules discovered on routine chest x-ray. Interestingly, the five-year survival for localized lesions of the lung was 45%.

An example of a patient with such a primary lymphosarcoma is presented.

Case Report

A forty-one-year-old white male was seen on a routine physical examination November 4, 1964. The patient entered the doctor's office for an annual physical examination as well as for investigation of a mass in the right submaxillary area, which had recently become noticeable but was asymptomatic. He had no other symptoms by history and system review.

The general physical examination was noncontributory except that there was a firm nontender mass in the submaxillary gland area on the right and one lymph node palpable in the right cervical area. Other lymph nodes were not enlarged. The chest, heart, abdomen, etc., were essentially normal. An electrocardiogram was also normal. The hemoglobin was 14.8 grams, the white blood cell count 11, 140; the differential cell count was 65% neutrophils and 35% lymphocytes; the sedimentation rate was 5 mm. per hour. The patient was wearing contact lenses because of bilateral cataract surgery in 1960 and 1961.

A routine chest x-ray was taken and demonstrated a coin lesion appearing as a round circumscribed mass in the right lower lung field. The chest x-rays of 1957 and 1961 were then reviewed. The lesion was definitely present, although 50% smaller in 1961. In the chest x-ray of 1957 the lesion was identified by "retrospective localization." The heart and lungs were otherwise normal.

Bronchoscopy and a right bronchogram were performed on January 15, 1965, and were interpreted

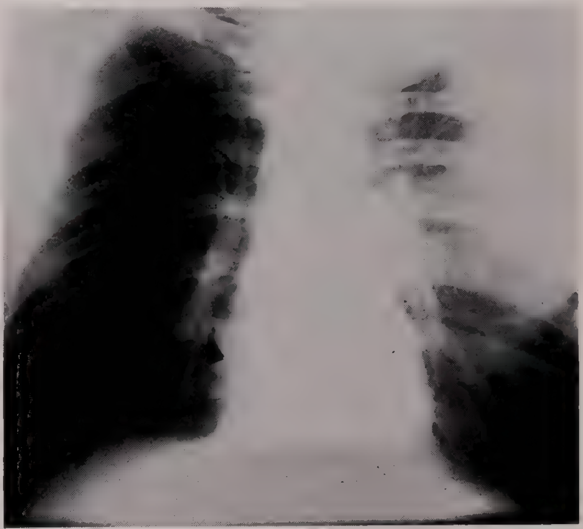

Fig. 1 — The standard chest roentgenogram demonstrates the round lesion (arrows) adjacent to the right inferior mediastinum. (November 4, 1964).

An Interesting Solitary Lesion of the Lung

J. T. GRISMER, M.D.
D. E. RAAB, M.D.
R. DORNBACH, M.D.
W. KRAFFT, M.D.
Minneapolis, Minnesota

as normal. The mass was at the bifurcation of the middle and lower lobes. Repeated sputum cytology studies demonstrated no evidence of malignant cells, and laminography demonstrated no calcium in the lesion.

An exploratory thoracotomy was performed on January 19, 1965, at which time a 3-cm. round, firm, brownish-red lesion was removed from the area of the bifurcation of the pulmonary artery into the lower and middle lobes. This lesion was directly adjacent to the bronchus and lay in the oblique fissure. Near it were several lymph nodes that were "normal" on histological study. In the region of the bifurcation of the trachea was a large mass of lymph nodes extending onto the left main stem bronchus as well as into the right main stem bronchus. The lymph nodes and the rounded lesion in the hilar area demonstrated the same histological pattern. The patient's postoperative course was essentially uncomplicated.

On January 25, 1965, the right submandibular lesion was removed as well as one other lymph node in the neck.

The pathological interpretation of the masses in the neck, the mediastinum and lung was "malignant lymphoblastoma of the nodular type (lymphosarcoma)." The patient received cobalt irradiation.

It is interesting to speculate that this man's primary lesion of the lung had been present since 1957, and was definitely discernible in 1961. In the absence of other localized areas of disease from the patient's numerous physical examinations, it would seem unquestionable that the primary lung lesion remained as such during these years. The eruption of similar lesions in the cervical area and in the mediastinum is puzzling. Such lesions might represent metastases from the original lesion in the lung but

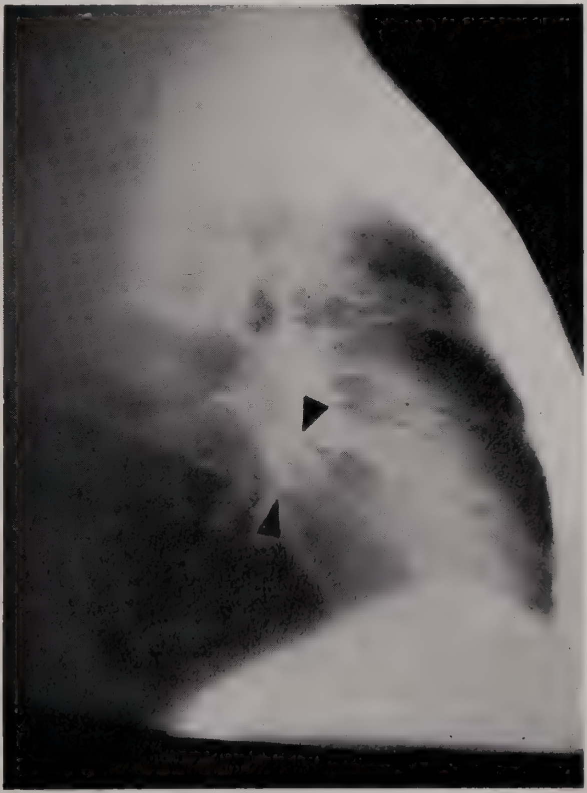

Fig. 2 — The right lateral chest roentgenogram illustrates nicely the relationship of the coin lesion to the division of the right middle and lower lobe bronchi. (November 4, 1964).

could actually be other primary foci that have arisen. The adjacent lymph nodes near the primary lesion in the lung were not involved by neoplasm. Likewise, the submaxillary area is not the usual drainage site for lesions within the lung.

Summary

An interesting case is presented of a 41-year-old white male with primary lymphosarcoma of the lung presenting as a coin lesion and with a known duration of three years.

CUSHING'S SYNDROME

Cushing has described three separate syndromes.

Cushing syndrome No. I is a multiglandular disorder ascribed to a basophilic adenoma of the pituitary. This may be recognized shortly after birth, but is most commonly observed in females during the child-bearing age.

The symptoms consist of fatigue, weakness, weight gain, nervousness, irritability, depression, and amenorrhea or menstrual irregularity. There is associated hirsutism with male distribution of pubic hair, thinning of the skin and well marked purplish abdominal striae. Acne may be present. The broad, moon-shaped face and obesity are largely confined to the head, neck and trunk and there may be a characteristic "buffalo hump" with hypertrophy of the clitorus, arterial hypertension, osteoporosis of the spine and pelvis, polycythemia, lymphopenia and mild insulin-resistant diabetes. There is a marked increase in the urinary output of 11-oxysteroids and a moderate increase in the 17-ketosteroid excretion. Most authorities now agree that the primary factor in this syndrome is an overactivity of adrenal cortex in which hyperadrenocorticism is bilateral in 60 per cent of the cases. The exact relationship of the consistent basophilic changes in the anterior pituitary to the adrenal overactivity is not known.

Cushing's syndrome No. 2 (Meniere's syndrome) is manifest by tinnitis, deafness, disturbances or loss of labyrinthine functions, hyperesthesia of the face, diminished corneal reflex and paresis of the facial and external rectus muscle. It is caused by involvement of the fifth, sixth, seventh and eighth cranial nerves, most commonly a tumor.

Cushing's syndrome No. 3 (Chiasmal syndrome). In this syndrome, there is bitemporal hemianopsia and gradual progressive failure of vision.

This is frequently the result of suprasellar meningioma or a primary intrasellar tumor. The prognosis of this condition depends upon the type of lesion and its accessibility for surgical removal.

Vein Stripping in Pregnancy*

FRANK W. QUATTLEBAUM, M.D.
JANE E. HODGSON, M.D.
St. Paul, Minnesota

In 1952 a series on vein stripping in pregnancy was reported by the above authors.[1] This work has been continued to the present time, with few changes since the original report. The current paper is a long-term follow-up study of the procedure and an evaluation of its present status.

During 1945 to 1950 a few early reports on vein stripping were being published in this country.[2-4,6,7] This old procedure was being revived because 25 years of experience with the saphenofemoral ligation had proved disappointing. At the present time vein stripping has become the accepted method of surgical treatment for incompetent veins. While this procedure offers no assurance of good results, it is the most satisfactory form of treatment available, provided it is properly done and the basic altered physiopathology is well understood.[5]

In 1948, after vein stripping had become routine treatment for incompetent veins, a few cases of severe varicose veins in pregnancy were referred to one of us (F. W. Q.) for treatment. Should these women, in marked distress from their varicosities, be given only bandages, injections, saphenofemoral ligation; or should they be given the identical treatment of the nonpregnant patients, i.e., routine radical vein stripping?

We elected to perform routine vein stripping. Rigid criteria for operation were adopted and have been followed for the past 15 years. These patients have been periodically surveyed, and the series has grown to 134 cases. Ninety patients of this group have been recently surveyed. The results, complications, and subsequent pregnancies of this group constitute this report.

Indications for Surgery in the Pregnant Patient with Varicose Veins

Before accepting a pregnant patient for vein surgery, we had to be assured that the patient had had incompetent veins in the nonpregnant state. A history of phlebitis in the pregnant patient with varicose veins and the severe sequelae associated with this complication constituted an additional indication for surgery.[8,9,10] The fourth to the seventh month of gestation was considered the most appropriate period, for by this time the signs and symptoms of varicose veins were advanced. Furthermore, the risk of fetal exposure to drugs, toxins, environmental changes, as well as incidence of spontaneous abortion, are greatest during the first trimester. Therefore surgery was delayed in every instance until the fourth month, and rarely performed after the seventh month.

Vein Stripping in General

For a better understanding of this disorder, a few basic facts should be explained to the patient before he undergoes surgery:

1. Varicose veins are a constitutional weakness, and therefore cannot be cured but only improved. Pregnancy is only one of several aggravating factors.

---

*Presented April, 1965 at the Minnesota Obstetrical and Gynecological Society Meeting in Duluth, Minnesota.

2. "Recurrences" (which are actually enlarging pre-existing veins rather than recurrences as such) are inevitable and follow-up care is essential. This is a life-long problem.

3. Although incompetent veins may be asymptomatic, they are nevertheless best treated by eradication in order to avoid the numerous potential complications which may ensue.

4. Symptoms are due to a hemodynamic disorder,[11] which medicine will not improve; elastic supports are temporizing, and injections are unsatisfactory except in the minor varices or branches. Eradication by radical stripping is the most satisfactory form of treatment.

Technical Considerations

The most important factor in obtaining good results in vein surgery is quantitative excision. Meticulous care in removing all incompetent veins, particularly the incompetent perforators, is most important.

Vein surgery should not be the time-consuming, laborious operation often depicted. By utilizing a planned, efficient procedure one can perform the average operation in less than one hour per leg.

In general, the surgical technique and postoperative care (Figure 1) are the same for the pregnant and the nonpregnant group. Pentothal anesthesia and intratracheal intubation and high O_2 flow are given to all patients. Complete eradication of the incompetent veins in the pregnant group requires a bit more time and diligence. The postoperative injection period is likewise more prolonged and tedious in the pregnant group. One finds, however, that after delivery, with consequent decreased venous pressure, the final results are excellent. In other words, the operator is less likely to overlook the small incompetent varix or perforator in the pregnant patient.

Postop.

1. Anticoagulants — If Indicated
2. Pressure Dressing — 6 Yd. Roll & Ace Bandages
3. Tub Bath with Dreft after 24 Hours
4. Thereafter Ace Bandages as the Only Dressings
5. Walk Ad Lib
6. Above Knee Supports 2 Wks.
   Below Knee Supports 4 Wks.
7. Injections If Needed
8. Return Every 6 Mos.

Fig. 1 — Postoperative vein stripping routine.

All of the nonpregnant patients should be given preoperative anticoagulants if there is a history of thromboembolic phenomena. Therapy should be continued postoperatively for varying periods of time.

Today, vein surgery is offered early as a prophylactic measure, whereas in the past, surgery was delayed until symptoms were severe.

Results

Previous thrombophlebitis with damaged deep veins will influence the results. Both the pre and postoperative evaluation will vary with the time of day depending upon the patient's activity.

As seen by Table 2, the final results of the pregnancy group collected over a 15-year period differ little from those of a group of nonpregnant patients reviewed consecutively in a period including 1957-58.

Of further interest in the pregnancy group is the incidence of full term pregnancies (Table 2). Of those coming to surgery, there was an average parity of 4.3 with an average

Vein Stripping

Patients	Subsequent Surgery	Pregnancies	Factors in Recurrence
152 Routine 1957-'58	14 %	———	Pregnancies Thrombophlebitis Follow-Up Failure
90 Pregnant 1948-'63	16.1%	Before Surgery 4.3 After Surgery 1.2	Pregnancies Thrombophlebitis (11%) Follow-Up Failure (22%)

Fig. 2 — Long-term comparative follow-up between routine vein stripping and vein stripping performed during pregnancy.

of 1.2 subsequent pregnancies after surgery. Indeed, of the 90 patients operated, 12 had three or more babies after surgery. Two thirds of the group had one or more babies after surgery.

Comments

This extended follow-up on this group of operated pregnant patients would seem to indicate that the results are comparable with those in the nonpregnant group. Their pregnancies were made more comfortable, and they were also less susceptible to complications of varicose veins during pregnancy by having had the immediate active treatment.

It would seem that it is not the best and most humane medical judgment to advise a young woman to defer vein surgery until her child bearing is over.

Sufficient time has elapsed to allow an adequate study of the children who were en utero during vein surgery. There was one intrauterine death which occurred a few days before term, etiology of which was indeterminate. This was three months following surgery. There are two children with mental retardation, one of whom is able to attend public school. The second child attends a special school and, in addition, has a congenital wrist drop. Two congenital defects among 89 live births is well within the expected range as outlined by the National Foundation.[12] Three and five-tenths per cent of live births have recognizable congenital defects. At the end of one year the incidence is raised to six and nine-tenths per cent.

Summary

A long-term survey of a group of patients undergoing vein surgery during pregnancy is presented. Their management and final results are compared with a series of nonpregnant patients having similar surgery performed by the same operator.

It is apparent that only a small percentage of pregnant patients have severe varicose veins and are candidates for surgery during their pregnancy. Careful selection of such patients is extremely important. When surgery is indicated, the patients can be made much more comfortable for the remainder of their pregnancy. The final results are satisfactory and compare favorably with those of the nonpregnant group. There appears to be no risk to mother or child if this procedure is carried out after the first trimester.

The Superior Man — Confucius (551 to 479 B.C.)

The superior man hates those who like to criticize people or revel in their weaknesses. He hates those who in the position of inferiors like to malign or spread rumors about those in authority. He hates those who are chivalrous and headstrong but are not restrained by propriety. He hates those who are sure of themselves and are narrowminded.

Idiopathic Hypertrophic

IDIOPATHIC HYPERTROPHIC subaortic stenosis, also known as muscular subaortic stenosis, is a condition in which there is an obstruction at the outflow tract of the left ventricle because of hypertrophy of the interventricular septum and free wall of the left ventricle. Although cases were reported prior to 1957, the entity has received increased investigation since that date. The following summaries of the clinical examination and cardiac catheterization data of three patients point out the pertinent features of this syndrome.

Case Reports

Case 1.

A 33-year-old male was discharged from the United States Navy in 1953 with a diagnosis of ventricular septal defect. This had not been verified by cardiac catheterization. He first noted anginal chest pain and dyspnea on exertion in 1956. Cardiomegaly was noted in 1964 (Figure 1); at this time a harsh grade iii/vi systolic murmur was heard at the left sternal border with radiation to the axilla and the neck.

The point of maximum impulse was in the fifth intercostal space midway between the anterior axillary line and the midclavicular line. The aortic second sound was present and was louder than the pulmonic second sound. Cardiac cinefluoroscopy demonstrated left ventricular enlargement and absence of intracardiac calcification. The electrocardiogram was interpreted as revealing left ventricular hypertrophy (Figure 2). A diagnosis of aortic stenosis was made and a thoracotomy performed in 1957. At operation the aortic valve was found to be normal.

The patient had a stormy postoperative course characterized by infection of the chest wall and the development of prominent Q waves in leads II, III and AVF. Since 1957 left-heart catheterization has been performed on three occasions and has shown left ventricular-subaortic peak systolic gradients of 30, 52 and 88 mm. Hg. respectively. Right-heart catheterization revealed a peak systolic gradient of 10 mm. Hg. between the right ventricle and

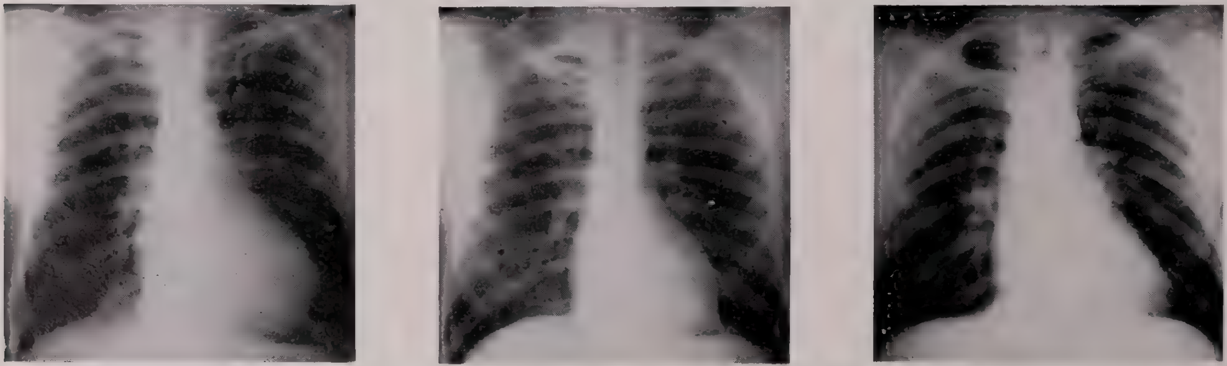

Fig. 1 — *Left.* Case 1. P-A chest x-ray taken in 1964. *Middle.* Case 2. P-A chest x-ray taken on admission. *Right.* Case 3. P-A chest x-ray taken on admission.

CARL S. ALEXANDER, M.D.*
Minneapolis, Minnesota

infundibular area of the right ventricle. A left ventricular angiogram demonstrated an S-shaped left ventricular cavity formed by the hypertrophied interventricular septum. Marked thickening of the free left ventricular wall was also present (Figure 3).

Case 2.

A 39-year-old male presented with a two-year history of exertional dyspnea, angina occurring at rest, and dizziness. A heart murmur had first been noticed eight years prior to the development of symptoms. Physical examination revealed a grade iii/vi systolic murmur at the left sternal border with radiation into the neck. The aortic second sound was normal. Radiologically, left ventricular prominence was noted (Figure 1), and on cinefluoroscopy, intracardiac calcification was absent. The electrocardiogram was interpreted as left ventricular strain (Figure 2), and the vectorcardiogram as left ventricular hypertrophy (Figure 4). Left heart catheterization was performed. There was no systolic pressure gradient between the aorta and left ventricle at rest, but following an Isuprel infusion a peak systolic gradient of 68 mm. Hg. was obtained (Figure 5). A peak systolic gradient of 128 mm. Hg. was noted following a premature ventricular contraction (Figure 5). Brachial artery and left ventricular pressure curves had peak systolic velocities which were increased in contrast to the pressure curves of aortic valvular stenosis, in which the first derivative of the brachial artery pressure curve is reduced.[1] Pulsus bisferiens** was present. A left ventriculogram revealed an outflow obstruction during systole. The aortic value appeared normal (Figure 6).

Case 3.

A 44-year-old male presented with a two-year history of exertional angina, dyspnea and dizziness, usually relieved by resting for a 20-minute period. The chest x-ray revealed left ventricular prominence (Figure 1). A grade iv/vi, harsh, medium-pitched systolic ejection murmur with radiation both to the neck and to the axilla was heard at the fourth intercostal space at the left sternal border. The aortic second sound was present. The electrocardiogram was consistent with ventricular hypertrophy (Figure 2) as was the vectorcardiogram (Figure 4). Left heart catheterization revealed a peak systolic gradient of 25 mm. Hg. at rest (Figure 7). A prominent atrial contraction was also noted. A left ventricular injection showed narrowing of the left ventricular cavity with marked hypertrophy of the left ventricular wall. The aortic valve appeared normal (Figure 6).

Discussion

This syndrome occurs in young adults of

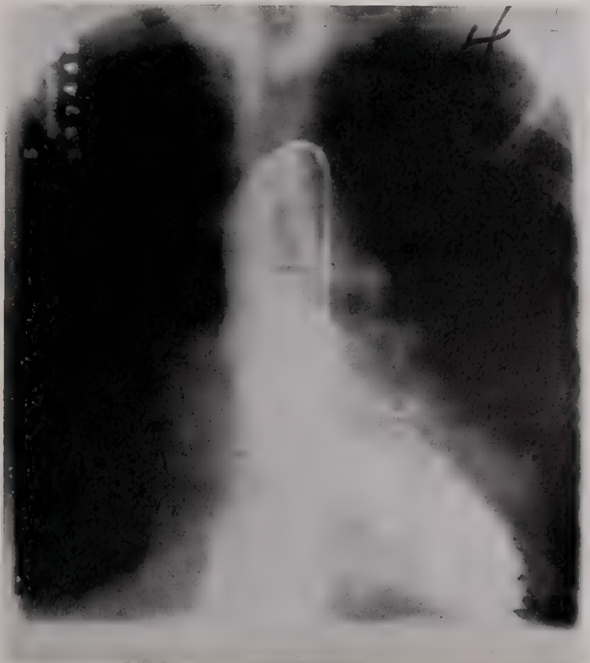

Fig. 3 — Contrast media has been injected into the left ventricle. There is increased thickness of the myocardium between the ventricular cavity and the lateral heart border. An area of narrowing in the left ventricular outflow tract is present overlying the spine.

either sex, although males predominate. Some of the cases have been familial.[2] Symptoms are generally progressive, usually consisting of dyspnea on exertion, anginal-like pains which are often atypical in nature, dizziness and syncope. A rare but characteristic symptom is the presence of dizziness or syncope following an episode of sneezing or paroxysmal coughing. The symptoms are thought to result from a hypertrophied, poorly distensible left ventricle with low muscular compliance. The lack of ventricular compliance presents an increased resistance to diastolic filling, raises the left atrial pressure and sets the stage for dyspnea. The left ventricular end-diastolic blood volume is low, resulting in a low stroke volume and a reduced cardiac output. A harsh, loud, medium-pitched systolic murmur, heard best at the left sternal border or apex, is always present and may radiate to the base or axilla. This murmur may be confused with aortic stenosis, interventricular septal defect or mitral insufficiency. In fact, mitral insufficiency is often concomitantly present. A mild amount

Fig. 4 — *Top.* Vectorcardiogram of Case 2. Initial forces are normal but the voltages are increased. *Bottom.* Vectorcardiogram of Case 3. Initial forces are normal but the voltages are increased. The mean QRS vector is more inferior in contrast to Case 2 in which it is posterior.

of right ventricular infundibular stenosis may also contribute to the development of the systolic murmur. A double apical impulse, pulsus bisferiens, a paradoxically-split pulmonic second sound, and third and fourth heart sounds are often present.[3]

The electrocardiogram is usually abnormal and generally demonstrates left ventricular hypertrophy. P mitrale is frequently recorded. Prominent Q waves are common in this condition and are thought to represent septal hypertrophy and not myocardial infarction.[3]

Radiographic studies show left ventricular and often some left atrial enlargement. Calcification of heart valves and coronary arteries is typically absent. Angiography demonstrates a narrowed ventricular chamber with thickening of the interventricular septum and free wall. The shape of the left ventricular cavity is usually abnormal.[4] The bulging interventricular septum results in an inward concavity at the mid-portion of the inferior border of the left ventricular cavity (Figure 3). In addition, a "tongue-like" extension of dye is seen extending to the apex of the left ventricle in the lateral view. Filling defects of the left ventricle are frequently seen and are due to localized hypertrophy of muscle. The coronary arteries are often dilated. The most characteristic finding is the presence of a cone-shaped narrowing which lies from 2 to 4 cm. below the aortic valve. The dimensions of this narrowed area vary during different portions of the cardiac cycle (Figure 6).

Cardiac catheterization data is necessary for diagnosis. There is a systolic gradient between the left ventricular cavity and the chamber above the hypertrophied muscle and below the aortic valve. This gradient is variable and is the result of several factors: the volume of the left ventricular cavity, the force of left ventricular contraction, and the transmural pressure which distends the outflow channel during systole. These factors are influenced by the presence or absence in the patient of basal conditions, anesthesia, muscular exercise, and medications. The administration of digitalis, Isuprel or nitro-

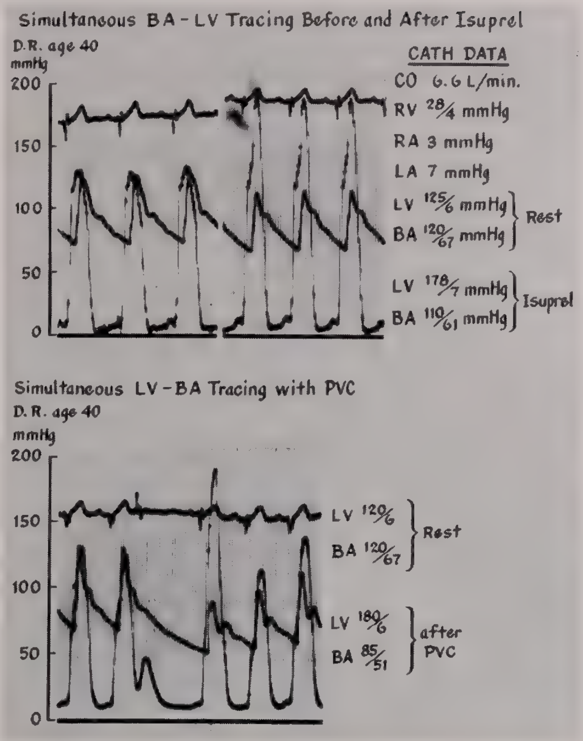

Fig. 5 — *Top.* Case 2. The electrocardiogram and the brachial artery and left ventricular pressures are recorded simultaneously before and after an isoproterenol infusion. A systolic pressure gradient of 68 mm. Hg. was obtained. Other data obtained during cardiac catheterization are listed at right. *Bottom.* Case 2. In the ventricular systole following a premature ventricular contraction, a peak gradient of 95 mm. Hg. is obtained. On another occasion a peak gradient of 126 mm. Hg. was noted. Following the premature contraction on the subsequent beat the brachial artery pulse pressure is also decreased, and several subsequent normal contractions are required before the brachial artery pressure returns to its previous level.

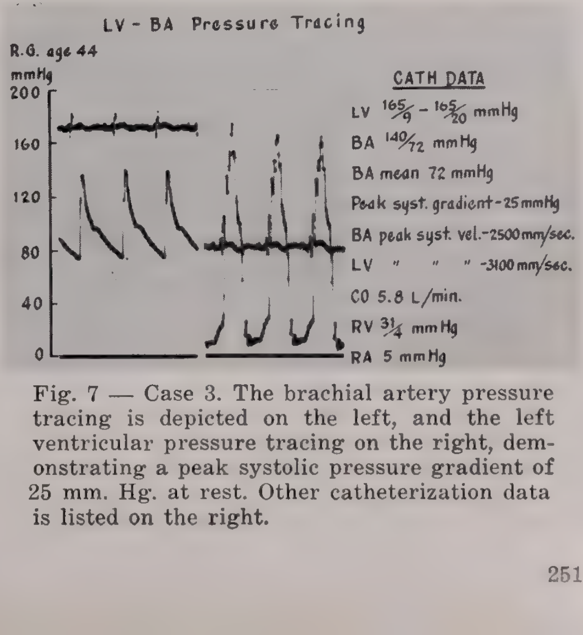

Fig. 7 — Case 3. The brachial artery pressure tracing is depicted on the left, and the left ventricular pressure tracing on the right, demonstrating a peak systolic pressure gradient of 25 mm. Hg. at rest. Other catheterization data is listed on the right.

glycerin accentuates the systolic gradient. When not present in the patient at rest, a gradient can be produced by the intravenous infusion of Isuprel,[5] or by the performance of the Valsalva maneuver.[6] This gradient is observed between the brachial artery and left ventricular pressure curves following a premature ventricular contraction[7] (Figure 5). A smaller gradient between the pulmonary artery and right ventricle is also demonstrable in some patients.

Treatment of this condition is difficult because the commonly used cardiac medications either cause no relief or tend to aggravate the symptomatology. The patient should avoid those activities which produce symptoms. Patients with more severe degrees of incapacitation have generally responded to

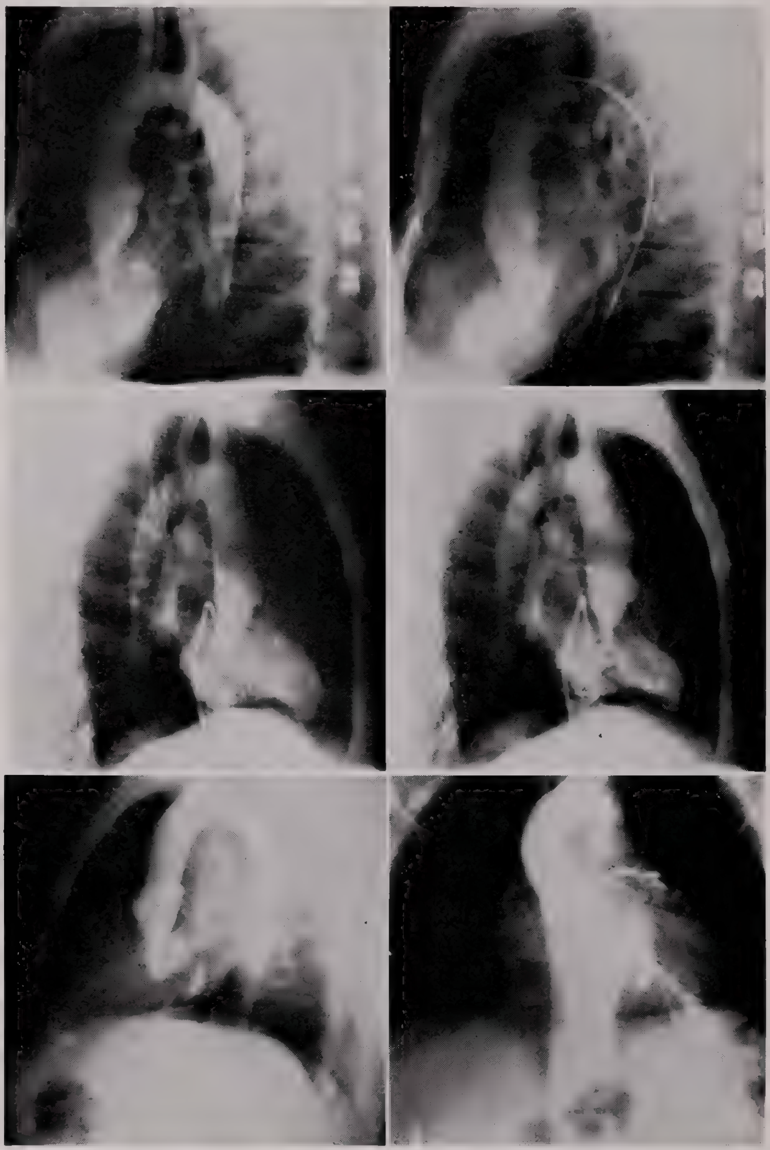

Fig. 6 — *Top.* Case 1. A cone-shaped area of stenosis can be seen approximately 4 cm. below the aortic valve. The dimensions of this stenotic area vary during different portions of the cardiac cycle *(right* and *left). Middle.* Case 2. Diastole is seen on the left, systole on the right. *Bottom.* Case 3. The stenotic area is seen as well as dilated coronary arteries. On the right is seen a "tongue-like" extension of contrast material extending toward the apex of the left ventricle. Hypertrophied myocardium almost obliterates the left ventricular cavity.

surgical removal of the hypertrophied septal tissue. Surgical mortality has been significant in the past and is the reason why more patients have not been operated. The most promising recent approach is one described by Morrow et al.[8] in which, under cardiopulmonary bypass, an aortotomy is performed and an incision made in the cardiac muscle from the stenotic area to the apex of the left ventricle, relieving the obstruction.

WHAT'S YOUR DIAGNOSIS?

A 64-year-old female was admitted to the hospital because of crampy pain in the abdomen of a six-day duration. She had vomited on one occasion shortly after having eaten lunch with her daughter the week before. They thought the vomiting had arisen from some food dyscrasia, because both she and her daughter had vomited. The vomiting did not recur, but she then became aware of abdominal distention. There had been no previous symptoms.

The examination indicated abdominal distention, active bowel sounds suggesting intestinal obstruction, and a large pelvic mass extending into the abdomen. The mass was fluctuant in the cul-de-sac but not tender. The abdominal portion of the mass was nodular and slightly tender. The admission temperature was normal, but during the next two days the temperature fluctuated from normal to 101°. The white count was 15,900. Polymorphonuclears-77%. Hemoglobin-14 grams. Sedimentation rate-24. BUN-35. Carbon dioxide combining power-21.8. Blood chlorides 89.5. The urine revealed 1+ albumin. X-ray examination suggested the possibility of small bowel obstruction. Barium enema revealed a large extrinsic mass in the pelvis causing a narrowing at the mid-sigmoid.

Gynecological and surgical consultations were obtained. The nodular abdominal mass and the pelvic cul-de-sac fluctuation were observed by both consultants. The patient was given Thyotepa in anticipation of a contaminating operation for malignancy.

Power

To have what we want is riches, but to be able to do without is power.
— George MacDonald

The Doctor and Literature*

Geoffrey Chaucer

Geoffrey Chaucer, a year before his death in 1400, lost his sinecure as Clerk of the King's Works. In the *Complaint of Chaucer to His Empty Purse,* the poet humorously petitions the new king, Henry IV, for a pension, ending with the lines:

"For which unto your mercy thus
I cry
Beth heavy again or elles must I
die."

Chaucer's Doctor of Physik is characterised as a verray parfit practitioner.

Eight years of study at Oxford were required to qualify for a medical degree in the Middle Ages. The students steeped themselves in the writings of famous physicians of antiquity — Greek and Arabian — ranging from Aesculapius to Rufus.

The Doctor of Physik, when treating a patient, first cast his horoscope. It was commonly believed in Chaucer's time that every man was born under one of the twelve planets of the zodiac. One might be born under the sign of Taurus the Bull, another under the sign of Pisces the Fish.

The worthy doctor cast his patient's horoscope to determine if the concatenation of the planets were at the moment beneficent or malign. This astrological lore determined the nature of the treatment given.

Chaucer's Doctor "knew the cause of everich maladye, were it hoot or cold or moiste or drye, and where engendred and of what humour." The doctor of physic prescribed drugs to be obtained from an apothecary.

There is a touch of malice in the last line of Chaucer's Cameo. During the pestilence or Black Death, the good doctor made a fortune by prescribing gold (aurem potabile) in his philters because, being avaricious, he loved gold above all things.

The distinction between the doctor and apothecary in the Sixteenth Century was not always clean cut. An apothecary frequently prescribed and filled a prescription in one operation.

John Milton

John Milton, from 1640 to 1660, when his poetic genius was at full florescense, sacrificed twenty years, his talent and his eyesight, to write political tracts of no literary merit for the Cromwellian government of which he was Latin Undersecretary of State.

When Charles II was restored to the throne, Milton's political pamphlets were publicly burned by the common hangman and the poet had to go into hiding until a general amnesty was declared.

Lord Byron

Lord Byron died in exile, the victim of what Thomas Babington Macaulay called the English public in one of its periodical fits of morality:

"Once in six or seven years our virtue becomes dangerous. We cannot allow the laws of decency to be violated. Some unfortunate man is singled out as an expiatory sacrifice. If he has children they are taken from him. If he has a profession he is driven from it. He is cut by the higher orders and hissed by the lower. He is in truth a sort of whipping boy. At length

Intraspinal Arteriovenous Anomalies

• Surgical
• Treatment

J. GRAFTON LOVE, M.D.*
HENDRIK J. SVIEN, M.D.*
HILLIER L. BAKER, JR., M.D.**
DONALD D. LAYTON, M.D.†
Rochester, Minnesota

THE PREVIOUS treatment of arteriovenous anomalies of the spinal cord has been largely disappointing. Since January 1963, four cases have been diagnosed at the Mayo Clinic by myelography and verified by thoracic aortography. The patients were treated definitively by intrathoracic occlusion of one or more anomalous arteries from the aorta which were feeding the intraspinal lesion. Each patient presented with various degrees of paraparesis, some with and some without sensory loss.

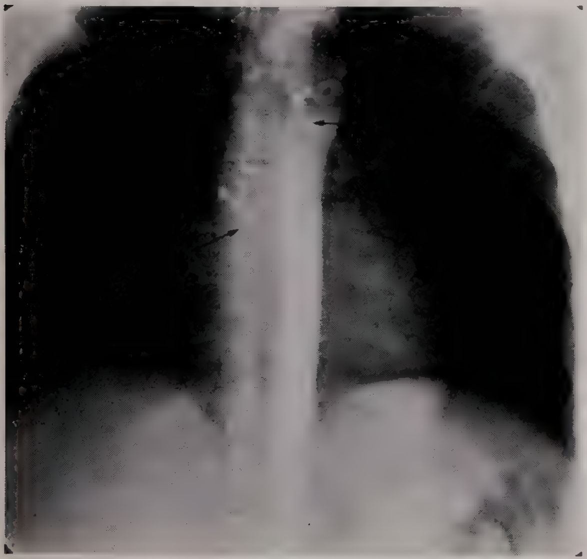

Fig. 1 — Retrograde aortogram showing two anomalous arteries: one on the left at the fourth space and another on the right at the sixth space feeding an arteriovenous lesion in the thoracic portion of the spinal cord. The opaque catheter in the aorta can be seen below.

At the time of this preliminary report the results of our surgical treatment are encouraging. What the long-term prognosis will be cannot be stated. We plan to follow these cases and to add others in a later report.

We feel that our combined efforts will help a far-from-small group of patients who, in the past, have had little to hope for and who, for the most part, have become paraplegic.

The following case illustrates the problem involved in the diagnosis and treatment of a vascular anomaly of the spinal cord.

Report of Case

A 21-year-old male college student had an insidious onset of lumbar backache which was aggravated by stress and strain. A diagnosis of lumbar muscle strain had been made and heat and analgesics had been applied. One month after backache began, while taking a shower bath, he noted that he could not feel the water over his left leg. Later he noted hyperesthesia over the right side of the chest at about the seventh and eighth dermatomes.

---

*Section of Neurologic Surgery, Mayo Clinic and Mayo Foundation.

**Section of Roentgenology, Mayo Clinic and Mayo Foundation.

†Section of Neurology, Mayo Clinic and Mayo Foundation.

We saw the patient about three months later. Myelography with Pantopaque had been carried out elsewhere. A protruded disk or neoplasm was suspected, but a diagnosis of a vascular anomaly of the spinal cord was made. The spinal fluid contained 100 mg/100 ml. of protein and the fluid was reported as being xanthochromic. In addition to the elevated concentration of protein, the fluid showed eight white blood cells and 68 red blood cells.

Physical Findings

Our examination disclosed hypalgesia at the level of the sixth and seventh intercostal spaces on the right. The loss was slightly lower and much more pronounced on the left. Loss of muscular power was not detectable, although the patient said that his left leg seemed weak. Some loss of thermal sensation was reported over the left flank. On auscultation over the spinal column, no bruit could be heard. There were no other obvious vascular abnormalities.

X-ray Studies

Roentgenologic examination of the spinal column revealed an old vertebral epiphysitis and residual opaque oil in the spinal canal. A retrograde aortogram by the Seldinger technique via the left femoral artery using 32 ml. of sodium and methylglucamine diatrizoates (Renovist) revealed two anomalous arteries from the aorta to the spinal canal and a pooling of opaque medium in large intraspinal veins in the thoracic region (Figures 1 and 2).

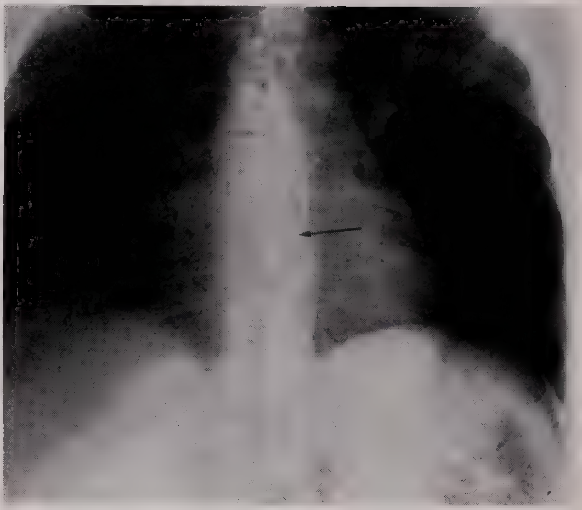

Fig. 2 — Extensive pooling of Renovist in abnormal veins in the subarachnoid space is seen (arrow) above the opaque catheter.

Thoracotomy was performed and the two anomalous arteries were occluded. The artery on the left at the fourth intercostal space was ligated and divided. The anomalous artery at the sixth space on the right was ligated but not divided.

The patient's convalescence was uneventful. The sensory deficit cleared and the feeling of weakness of the left lower extremity disappeared. He was dismissed eight days after the operation.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(from page 253)

Pelvic abscess, appendical in origin; multiple myomata of the uterus. The confusing nodularity of the abdominal mass had led all of the examining physicians to the erroneous diagnosis of carcinoma of the ovary.

Have Faith

Dr. Carl Jung, famous psychiatrist, once told a sick patient that he was suffering from a lack of faith in God and immortality. The young man asked, "But, Doctor, do you believe in God and immortality?" Dr. Jung replied: "I am a doctor, not a priest. But I tell you this: If you recover your faith, you will get well; if you don't, you won't."

Bilateral Vocal-Cord Paralysis

Post Thyroidectomy Surgical Correction

BENJAMIN BOFENKAMP, M.D.
Minneapolis, Minnesota

ALTHOUGH VOCAL-CORD paralysis may result from numerous causes, the most frequent cause of bilateral vocal-cord paralysis occurs from injury to the recurrent laryngeal nerves during thyroidectomy. This unfortunate surgical complication results in an inadequate laryngeal airway and a poor speaking voice. This article presents a surgical procedure which has been successfully employed by the author in twelve cases with very satisfactory results. The procedure assures an adequate airway and a useful voice.

The surgical technique was originated and explained to me by William C. Thornell, M.D., in 1952.[1] Prior to that time, like others, the author had employed various other surgical procedures which had been advocated for the surgical management of bilateral vocal-cord paralysis. These operations were successfully applied and advocated by King, Kelly, and Woodward along with other surgical modifiers. The author adopted the Thornell intralaryngeal technique because surgically it was far less complex but just as successful as the extralaryngeal approaches advocated by those before Thornell.

Bilateral Cord Paralysis

Most postoperative thyroid gland vocal-cord paralysis is unilateral and presents no serious problem, as an adequate airway exists because the opposite unaffected cord has normal excursion. The only problem resulting from a unilateral vocal-cord paralysis is hoarseness. In a bilateral vocal-cord paralysis the vocal cords are often fixed in a median line position, thereby establishing an inadequate airway (Figure 1 a, b). The patient is in an extremely critical condition and often requires an immediate tracheotomy. In some cases the median fixation of the vocal cords is not complete and a small laryngeal opening

Fig. 2 — Exposure of larynx.

leaves the patient with a very restrictive airway. In such cases, any exertion results in marked dyspnea with stridorous breathing and inability to climb a flight of stairs without experiencing respiratory embarrassment. Furthermore, patients often cannot tolerate the laryngeal edema that accompanies an acute respiratory infection and will require an immediate tracheotomy in order to provide a proper airway.

It is now generally agreed that a patient who has a bilateral vocal-cord paralysis resulting in an inadequate airway which has existed for a period of at least six months should be a candidate for surgical improvement of the airway. The following descrip-

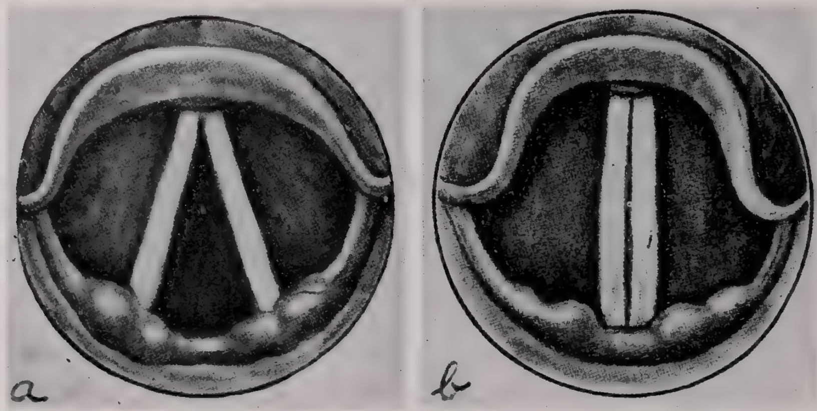

Fig. 1(a) — Position of vocal cords in normal larynx (inspiration). (b) Position of vocal cords in bilateral mid-line paralysis.

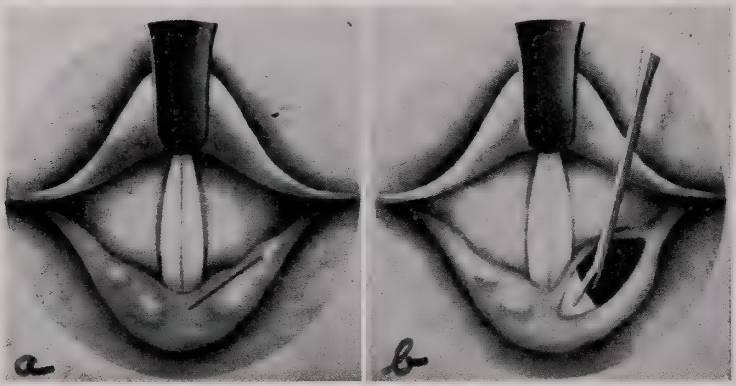

Fig. 3(a) — Incision over the arytenoid cartilage. (b) Arythenoid cartilage immobilized and denuded.

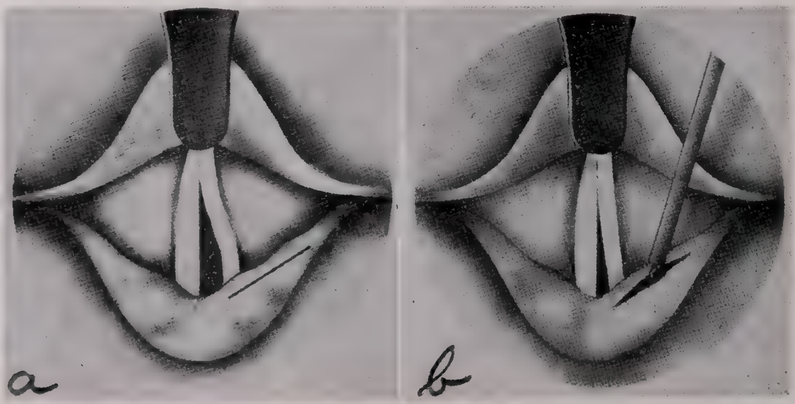

Fig. 4(a) — Position of vocal cords after right arytenoidectomy. (b) Electrocautery applied to lateral area of wound.

tion of the surgical technique of intralaryngeal arytenoidectomy* is the one which has been successfully applied by the author in twelve consecutive cases.

Surgical Procedure

Preliminary Tracheotomy

If the patient has not required a previous tracheotomy, this procedure is performed prior to the arytenoidectomy, the two procedures being scheduled together. The tracheotomy may be performed under local anesthesia, but I prefer to perform it under intralaryngeal general anesthesia and then proceed with the arytenoidectomy. In that manner, one can proceed immediately following the tracheotomy to the arytenoidectomy without interruption from the anesthesiologist and without breaking scrub technique.

Exposure of the Larynx

Following tracheotomy, the larynx is exposed by the Killian-Lynch suspension laryngoscope. A very adequate exposure of the larynx is obtained with this instrument and it affords the best visualization of the larynx by means of an operating headlight (Figure 2). After the larynx has been exposed, the operator chooses the cord upon which the arytenoidectomy is to be performed. Either cord may be selected. Being left-handed, the author has experienced more surgical ease in removing the right arytenoid and has observed that the right-handed operator is more agile in approaching the left arytenoid.

Removal of Arytenoid

Having selected the arytenoid to be removed, the corresponding aryepiglottic fold is slowly infiltrated with approximately two cc. of one per cent Xylocaine with epinephrine. As in septoplastic surgery, this infiltration serves two purposes; it minimizes the bleeding and aids in the elevation of the soft tissue from the arytenoid cartilage. Following infiltration, an incision is made over the arytenoid cartilage until its superior surface is exposed (Figure 3-a). The cartilage is grasped and immobilized, thereby enabling the operator to separate all muscle attachments from the arytenoid cartilage (Figure 3-b). This cartilage, having been denuded, is severed from its articulation with the cricoid cartilage and removed.

Results

Following disarticulation, the vocal cord promptly assumes a position lateral to the mid-line, thereby giving the desirable airway (Figure 4-a). In seven of the cases operated by the author an obturator was introduced between the vocal cords to approximate the wound edges as suggested by Thornell. The five other cases were just as effectively managed minus the obturator, providing electrocautery was applied to the lateral area of the wound (Figure 4-b). Electrocautery produces scarring and assures lateral fixation of the vocal cord. Postoperative edema is well controlled by the proteolytic enzymes, and the patient may have a liquid diet within twelve hours postoperatively.

The tracheotomy tube may be removed on the third to fifth postoperative day and the patient discharged two days afterward.

Comments

The author has experienced successful results in twelve consecutive intralaryngeal arytenoidectomies affording an adequate airway and better speech to those with bilateral vocal-cord paralysis.

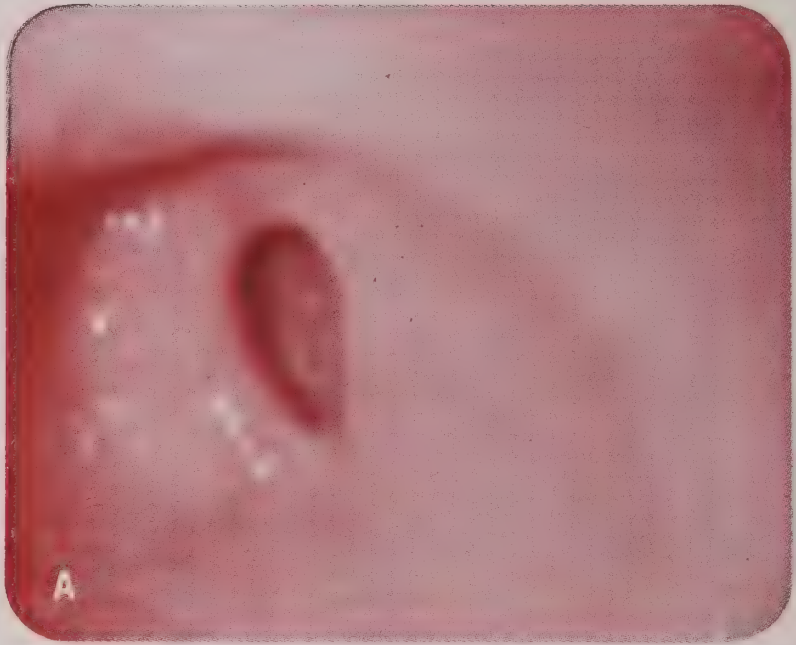
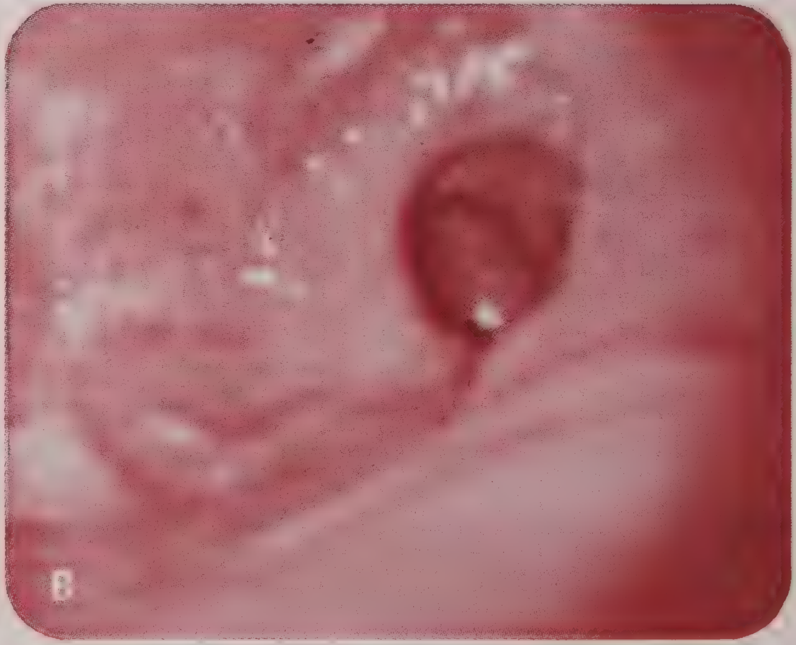
Accomplishment

I have enormous respect for anyone who has accomplished anything, anytime, anywhere — Solomon Papper, M.D., Dept. of Medicine, University of New Mexico School of Medicine, Albuquerque.

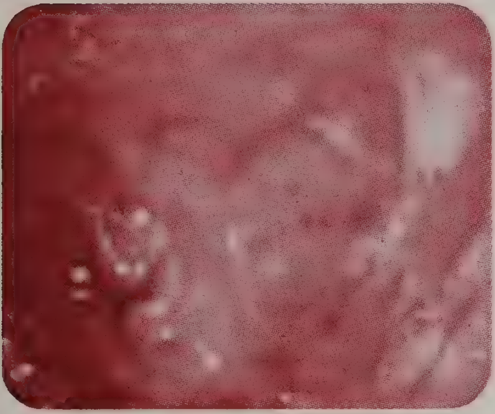


Which Is Pyloroplasty with Vagotomy?
Which Is Pro-Banthīne?



Photographs—Harry Barowsky, M.D., Lawrence Greene, M.D., and Robert Bennett, M.D., from a Scientific Exhibit presented at the Annual Meeting of the American College of Gastroenterology, Bar Harbour, Florida, Oct. 24-27, 1965.

Another example of
Pro-Banthīne®
(propantheline bromide)
a true anticholinergic in action



Normal relaxed pyloric antrum; contracted pylorus (pyloric fleurette)

The true anticholinergic values of Pro-Banthīne have never been so graphically realized as they are with the recent development of fibergastroscopy and the intragastric camera.

Pro-Banthīne consistently produces complete relaxation and immobility of the stomach with a dose of only 6 to 8 mg. intravenously. This is less than half the usual dose orally.

Atropine, on the other hand, required 0.8 mg. intravenously, or twice the normal dose, to achieve a similar effect. This high dose of atropine resulted in expectedly adverse side effects.

Pro-Banthīne, in minimal dosage, produces effects similar to pyloroplasty and vagotomy without the disadvantages of permanent postvagotomy sequelae.

The intragastric photograph A is of a patient who has had pyloroplasty with vagotomy. Photograph B is of a patient given 6 mg. of Pro-Banthīne.

Indications: Peptic ulcer, functional hypermotility, irritable colon, pylorospasm and biliary dyskinesia.

Oral Dosage: The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type ampuls of 30 mg.

Side Effects and Contraindications: Urinary hesitancy, xerostomia, mydriasis and, theoretically, a curare-like action may occur. Pro-Banthīne is contraindicated in patients with glaucoma, severe cardiac disease and prostatic hypertrophy.

Bone Marrow Aspiration and Biopsy*

STRIKING AND challenging applications of fluorescence microscopy, isotope techniques and other physical and chemical advances to the study of hematology are now in use. However, morphologic interpretation of the bone marrow retains its fundamental importance to the clinician, hematologist, pathologist, and researcher alike. In 1929 Arinkin[1] proposed aspiration of bone marrow from the sternum for biopsy purposes.

The major growth in the clinical application of marrow aspiration technique has come since the Second World War. Much of the credit for stimulating interest in and encouraging the use of this relatively simple, but valuable, procedure by the local medical community must go to Emil M. Schleicher, Ph.D.* He describes methods for cytologic and histologic preparation of the bone marrow particles which seem rather time consuming. However, they are second to none when one considers the quality of the preparation presented to the pathologist or hematologist for interpretation.

A disadvantage of the technique outlined by Schleicher is the large quantity of marrow desired. Many authors feel that this, of necessity, involves dilution of the marrow sample by sinusoidal blood. A moderate quantity of aspirate is, of course, desirable for the conventional method of bone marrow processing. This involves preparation of Wright's-Giemsa stained smears from the buffy coat plus separation of the bone marrow particles for histologic study.

A complementary method which has recently become a part of our bone marrow aspiration routine is the "supravital" technique as outlined by Sabin,[2] Doan and Ralph.[3] This involves staining of the "living" fluid marrow with neutral red and jannus green. "Supravital" methods are used extensively by the hematology group at Ohio State University.

The routine use of "supravital" techniques often allows a definitive diagnosis to be reported within minutes after the specimen reaches the laboratory. Iron stores can be evaluated without the need for special stains. Frequently, more accurate classification of the acute leukemias can be made. Watching the formation of L.E. cells in vitro is a fascinating experience.

The aspiration techniques are the methods of choice provided a suitable specimen can be obtained. However, in certain situations, not any or only a few bone marrow particles

An antibiotic of choice is one that works

TAO works

Susceptibility Results
Staphylococci [2,3,1]

# OF CULTURES	YEAR	% EFFECTIVE
6,725	1962	88.6%
5,440	1963	88.0%
10,384	1964	88.5%
β-Hemolytic Streptococci [2,3,1]		
2,448	1962	89.5%
1,519	1963	95.2%
2,492	1964	96.7%

The Product

In a world study of antibiotics ***in vitro***[1], TAO had an overall effectiveness of 87.3%, higher than chloramphenicol and erythromycin, and significantly higher than tetracycline and penicillin.

The Plus... Consistent Performance

Yet antibiotics must not only work. They must work consistently. Here are the results from the largest study of microbial susceptibility ever undertaken. In 29,048 cultures of overt staphylococcal and β-hemolytic streptococcal infections, note the consistency of results with TAO.

TAO®
[triacetyloleandomycin]

J. B. Roerig and Company, New York, New York 10017
Division, Chas. Pfizer & Co., Inc., Science for the World's Well-Being®

TAO Rx information

Indications: The bacterial spectrum includes: streptococci, staphylococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents. **Contraindications and Precautions:** TAO (triacetyloleandomycin) is not recommended for prophylaxis or in the treatment of infectious processes which may require more than ten days continuous therapy. In view of the possible hepatotoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents, of course, should be used. If clinical judgement dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. It is contraindicated in pre-existing liver disease or dysfunction, and in individuals who have shown hypersensitivity to the drug. Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions. **References:** 1. Isenberg, Henry D.: Health Laboratory Science **2**:163-173 (July) 1965. 2. Fowler, J. Ralph et al: Clinical Medicine **70**:547 (Mar.) 1963. 3. Isenberg, Henry D.: Health Laboratory Science **1**:185-256 (July-Aug.) 1964.

are forthcoming. This is the so-called "dry tap." According to McFarland and Damashek,[4] a "dry tap" may be anticipated in about 6% of marrow aspirates. In the hands of an experienced operator, thoroughly familiar with the aspiration techniques, a "dry tap" is an almost certain indication of serious disease of the marrow organ. Until recently this problem had to be resolved by resorting to surgical trephine with its attendant need for an operating room, probable general anesthesia, and the services of a general surgeon, all of this resulting in added patient morbidity and expense.

Since 1958, several papers have appeared reporting successful results with posterior iliac spine puncture using the Vim-Silverman needle or various modifications of this instrument.[4-7] This technique gives promise of eliminating the need for surgical trephine in most cases.

The specimen obtained with the Vim-Silverman needle is usually 1½ to 2 cm. in length and up to 0.2 cm. in diameter. After a brief decalcification, it can be processed in the same manner as a surgical specimen. The results have demonstrated a specific lesion of the bone marrow in many instances. Silver[6] indicates that in 50% of 266 cases of granulomatous or malignant diseases involving the marrow this biopsy method was the only technique yielding the diagnosis.

The methods of marrow biopsy are simple and in the hands of experienced operators carry virtually no risk. Injudicious use of the sternal aspiration by an inexperienced physician may be hazardous. Bakir[8] recently reported one case and reviewed nine others in which death resulted from through and through perforation of the sternum and pericardium. The fatal outcome in these cases was either demonstrated to be, or clinically suspected to be, cardiac tamponade secondary to hemopericardium.

Many times the study can be demonstrated to be unnecessary by an examination of the peripheral blood morphology. In some situations, other hematologic methods might be productive of more useful information. Also, in an effort to keep the technicians in the hematology section on his side, the clinician is wise if he schedules the procedure as far in advance as possible. In only the most unusual of circumstances should such a biopsy have to be done "stat." As with most other well-controlled laboratory techniques, a bone marrow biopsy interpretation depends upon the quality of the specimen presented to the hematology department.

Advances in Scanning

IT IS INEVITABLE that rapid changes in the fields of electronics and radiochemistry should make their impact in the field of nuclear medicine. Just a few years ago, isotopic studies in clinical medicine were by and large related to the study of iodine metabolism by the thyroid. It was only natural that some one should want to plot the distribution of the radionuclide within the target organ, and the thyroid, being the organ most suitable then for study, became the subject of early scanning procedures.[1] Indeed, to

Continued

PENTAZYME
DIGESTANT

An eight-year-old may not need digestive enzymes . . .

BUT troublesome gas, belching and cramps are common complaints of many patients regardless of age. PENTAZYME will give these patients fast relief when the diagnosis is enzyme insufficiency.

PENTAZYME offers 5 supplemental digestive enzymes in *one* enteric-coated tablet for release at the natural sites of action. Three tablets, the usual daily dose, will digest 50% of the starch, 40% of the protein and 20% of the fat in a balanced 2500 calorie diet.

For patients with short-term or chronic digestive problems, prescribe PENTAZYME.

For complete information and samples, write to Dept. MM-100

this day, the use of the unqualified terms, "uptake studies" and "scanning" by many practitioners in the clinical fields refers to the thyroid gland.

Recent changes, however, have brought about a veritable mushrooming of interest and applicability in the use of radioisotopic scanning. As demonstrated in an accompanying article in this issue by Loken, Telander and Laxdal,* improvements in the art of nuclear medicine are taking place along two major fronts. The first is the development of new radiopharmaceuticals and the second is the emergence of vastly improved detection and recording devices.

The radiopharmaceutical** of choice depends on the organ being scanned, and many different varieties are presently available. However, it is rapidly becoming apparent that in the near future 99m-Technetium may become the universal agent of choice. In the pertechnetate form it is useful for scanning the brain and thyroid. Appropriate modification of the pertechnetate ion will result in agents useful in scanning the liver, spleen, placenta and kidney. Along with its seeming universality are the marked advantages of being able to administer large doses (up to 10 mc.) in order to obtain good counting "statistics" thereby improving the scan image, and still deliver radiation dosage comparable to or lower than that received from agents currently being used.

One of the major drawbacks of present day scanning is the time required to obtain a satisfactory study. The scintillation camera, referred to in Loken's paper, is an example of one of the second generation of scanners and frees the unit from the physical limitations of moving heavy shielded detectors in a rectilinear fashion. Scanning in this mode is performed electronically and reduces the time necessary to a matter of a few minutes — an obvious advantage in clinical practice. This now opens the way for dynamic studies of blood flow, function studies and studies of other processes not heretofore available.

It is apparent that the vast growth in the literature for scanning procedures reflects recent technological and pharmaceutical developments. Looking more closely to home, one finds the number of scanners in use in the state of Minnesota to have risen from 20 in 1964 to 28 in 1965.[2]

Lest the casual reader become too complacent about the high level of performance now obtainable, one has only to reflect upon the fact that "exposure" times now in effect with the best instruments approximate that which was necessary with the roentgen tube shortly after the turn of the century, but a scan image has yet to contain the total number of "bits" of information conveyed on those old glass x-ray plates of the early 1900s.

Responsibility

Don't fret over what the world owes you. Stew over what you owe the world.

— Forbes

She's on a diet.
She's discouraged.
She needs your help.

You can encourage her with DEXAMYL®
brand of dextroamphetamine sulfate and amobarbital

'Dexamyl' is the mood-lifting anorectic; it not only assures unexcelled control of appetite but also improves outlook.

Formula: Each 'Dexamyl' Spansule® (brand of sustained release capsule) No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid [Warning, may be habit forming]. Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital [Warning, may be habit forming]. *Principal cautions and side effects:* Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Insomnia, excitability and increased motor activity are infrequent and ordinarily mild. *Before prescribing, see SK&F product Prescribing Information. Smith Kline & French Laboratories, Philadelphia* SK&F

Coronary Blood Flow

We draw our reader's attention to further evidence that nitroglycerine relief of angina pectoris is not explainable by measurable increases in coronary flow (Cohen et al.),* notwithstanding the demonstration of coronary dilatation on arteriograms after nitroglycerine. There is evidence that nitrites produce a fall in systemic and venous pressure, and a decrease in cardiac work, factors which may explain their beneficial effects in the absence of an increased coronary flow.

Cohen and his colleagues propose the use of a test of the effect of nitroglycerine on coronary flow, measured with radioactive rubidium 84, to distinguish between normals, who exhibited an increase in coronary flow, and patients with coronary disease, who did not. The value of this method will be determined by confirmation of these results in much larger test groups.

Pyoderma Gangrenosum

Altman and Mopper* present a concise report concerning the rare chronic ulcerative skin disease known as pyoderma gangrenosum which was first described by Louis Brunsting,[1] recently retired as head of the section of dermatology at the Mayo Clinic. Altman and Mopper state that the sulfone drugs, particularly diaminodiphenylsulfone (avlosulfon), are effective in the treatment of pyoderma gangrenosum. The authors agree with Brunsting and his coworkers that the control of any underlying disorder such as ulcerative colitis is important. Altman and Mopper believe that the sulfone drugs do not produce allergic cross reactions with the sulfonamides and appear to be well tolerated in patients who are sensitive to sulfonamides. An encouraging response to the administration of gamma globulin has been reported by Bloom and his associates.[2] Baer and Kopf[3] of the New York University Schools of Medicine believe that patients who have pyoderma gangrenosum may respond well to corticosteroids even after therapy with gamma globulin has failed. The possibility that autoimmunity plays a role in the pathogenesis of the disorder deserves study.

Neonatal Gastric Rupture*

Rupture of the stomach is probably less rare than the literature would lead one to believe. Few clinicians report their failures except in association with their successes.

While the cause cannot be pinpointed, several mechanisms undoubtedly play a part. Distention, which is present from time to time in all infants, probably is a major factor in thinning out the gastric wall; this compromises the circulation and reduces the stom-

to help relieve pain
in common
anorectal disorders

"non-caine"
Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE®
OINTMENT
Soothing, Temporary Relief of Hemorrhoidal Pain, Rectal Itching

CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Merrell

ach's ability to resist both the sudden tensions of vomiting, straining, crying and various external forces and the progressive build up of intraluminal pressure from air swallowing and forced feeding. The effect of gastric juices during this set of unfavorable circumstances can only be surmised. Anoxia would seem to augment the effects of compromised circulation.

Curiously, duodenal blockage is rarely associated with gastric rupture. There appears to be some reflex mechanism in this situation, which produces relaxation of the esophagogastric junction and thus permits easy and often effortless eructation of gas and fluid.

Diencephalic lesions are repeatedly mentioned as the cause of gastric ulceration. While this mechanism probably exists, it seems to have little relationship to the massive lacerations so often encountered in neonatal rupture of the stomach.

The trauma of the passage through the birth canal is the most likely source of peak pressure within the lumen of the stomach. It must be assumed that the layers of the stomach rupture at varying tensions and this variation may explain the extensive laceration often encountered with only modest necrosis of the wound margins in an infant who had appeared reasonably normal and vigorous during the first 36 to 48 hours of life.

Silbergleit and Berkas are to be commended not only on their success in solving their clinical problem but also on their efforts to throw light on a very poorly understood entity.

Early detection and immediate operation without unnecessary studies provide the major hope for success in cases of neonatal gastric rupture. The use of a gastrostomy as a postoperative safety vent is to be urged; however, in many of these ruptures there is little area on the anterior surface of the collapsed stomach available for establishing a satisfactory stoma.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

WALLACE LABORATORIES
Cranbury, N.J.

CM-8761

The Physician's Gethsemane

The doctor's responsibility is an onerous, momentous, and sometimes an awesome one. In his profession the physician is not engaged with stable, tangible commodities; instead, he deals with inconstants and imponderables: the unpredictable responses of a diseased or damaged human body. He is faced with solving an equation whose terms are relatively unknown quantities.

It is incumbent on him to exert the last full measure of his professional and humanitarian capacity, not only to achieve the physical recovery but also to assure the emotional and mental stability of the patient and his satellites.

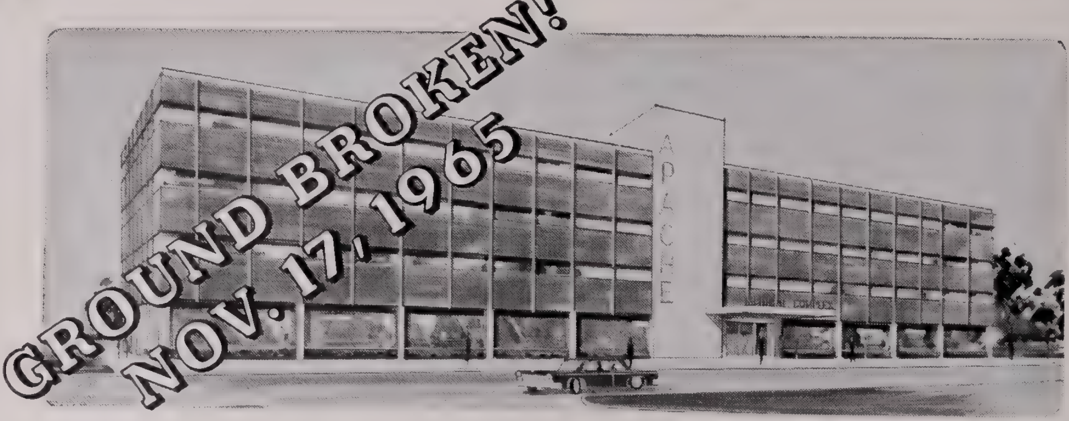
In his single-minded crusade to restore health and conserve life, the physician is a perfectionist and idealist, for whom the best scientific procedure is the only morally admissible one.

During every critical illness or operation there are moments, hours, or sometimes days when a patient floats unsteadily in the balance between life and death; and throughout the patient's delirium the physician searches for the slightest sign of improvement or decline, clues for deciding whether or not to prescribe, to initiate or to defer action, to adopt aggressive or even heroic measures.

He rechecks and reviews; his observations seem incredible; he walks the hall and paces the staff room. To a passing doctor he describes the clinical phenomena; to an anxious intern who has relied on him for previous instructions and advice he relates his findings. He is at liberty to call on any one of his numerous colleagues and this he does. He knows that consultation leads to additional ideas, that it divides his grave responsibility and gives him assurance that he is carrying out the procedures that are in accord with the most modern medical knowledge. If a consultation with one physician cannot resolve the quandary, then another colleague can be called. All physicians are eager to help in restoring life and health to the individual who at the moment is occupying the center of the stage.

In the unfortunate circumstance over which the physician may have had no control, where a series of complications may have arisen in the course of an illness, he is especially challenged; for it is here that his moral and ethical judgment guides him to seek additional advice. If the consultants are essentially unanimous in their decision, no serious problem confronts the attending doctor; and regardless of the outcome of the patient's illness, the unanimous opinion of consulting physicians gives him assurance that liability has been discharged. In the absence of unanimity, however, he stands alone and must remain the final arbiter. If he succeeds he has rendered an invaluable service or he has done no more than was expected of him. If, on the other hand, he fails, he appears to have failed not only his patient but the whole constellation of family, kindred and friends, perhaps even himself and his profession; and failure in no other area of human service is so totally and tragically irreversible as it is in the medical field.

Only when the crisis has passed and the patient is out of danger can the doctor relax, knowing full well, however, that it could have been otherwise. When recovery is assured, he can feel vindicated — but not for long. Tomorrow he will again stand alone beside another patient on the precarious hairline between living and dying — another case to try his mettle and test his morale. His is a lonely job! — Carl O. Rice, M.D.



GROUND BROKEN!
NOV. 17, 1965
APACHE

APACHE PLAZA MEDICAL COMPLEX

"Standing in the middle of a boomtown in the North . . . in the middle of a 'doctor-poor' area"—*Mayor James McNulty, St. Anthony Village, in a speech at the ground-breaking ceremony for Apache Plaza Medical Complex, November 17, 1965.*

You're right, Mayor McNulty. That's why Apache Corporation's Real Estate Division decided to build a medical complex at Apache Plaza.

We knew the statistics. While the five-county metropolitan area population was growing 13.8 per cent from 1960 to 1965, the population in the area served by Apache Plaza grew 47 per cent.

We knew the Apache Plaza area statistics on doctors, too—one g.p. for each 4,100 people, one ob-gyn for each 21,000 persons, and one pediatrician for each 17,000. And we knew that there weren't enough doctors—because our customers told us many times that the small medical facility we now have just wasn't big enough. We know another thing—the growth in this "boomtown" area, northeast of Minneapolis and northwest of St. Paul, is going to continue.

Doctors are needed. And Apache is going to offer doctors the finest medical facility in the Upper Midwest. So, Doctor, if you'd like to practice in boomtown, in a modern medical building with ample parking, pathology and radiology labs, essential ancillary services, and totally flexible space-planning, call or write:

Our Senior Educators

Cecil J. Watson, M.D.

In 1961, Cecil James Watson, the current Chairman of the Department of Medicine at the University of Minnesota School of Medicine, received the James F. Bell Distinguished Service Award of the Minnesota Medical Foundation and at that time was named Distinguished Service Professor.

Dr. Cecil Watson was born in Minneapolis, Minnesota. His father, James Alfred Watson, was born in Ireland and emigrated to Canada at the age of 16. He graduated in medicine from the University of Manitoba in 1895. For a time Dr. James Watson practiced medicine at Wood Lake, Minnesota. After post-graduate study in diseases of the eye, ear, nose and throat in New York and in Vienna, he returned to practice this specialty in Minneapolis for many years. Dr. Cecil Watson's mother was Lucia Coghlan, also of Irish descent. The Coghlans were early settlers in Minnesota near Wood Lake; it was there that Mrs. Watson was born.

Dr. Cecil Watson grew up in the Kenwood District of Minneapolis and

Continued

attended grade and high school in that locality. He enrolled at the University of Minnesota with the intention of taking premedical training but has indicated on several occasions that his initial interest was actually in English and French literature and writing. For a time he seriously considered a literary career and was not immediately attracted to science. Fortunately his interest in science grew as he took more courses in chemistry. He enrolled as a freshman medical student at the University of Michigan in 1921 and returned to Minneapolis to complete his medical training at the University of Minnesota. Dr. E. T. Bell, Professor of Pathology, had a profound influence on this medical student, and it was under Dr. Bell's guidance that Cecil Watson developed an interest in pathology. He first took a Master of Science degree in that subject. His thesis dealt with periarteritis nodosa, a disease that at that time had not received a great deal of attention. Dr. Watson's first published scientific paper was unique, for he described the earliest recognized case of histoplasmosis in the United States. Darling had reported three cases in the Panama Canal Zone twenty years earlier. As a member of the Department of Pathology, Dr. Watson had performed an autopsy on a woman who had always lived in Minnesota. After detailed study of the case and a review with Professors Hal Downey and Riley, he was able to identify the organisms in the tissue sections.

After graduating from the University of Minnesota Medical School, Dr. Watson obtained a Ph.D. degree in the Department of Pathology under Dr. E. T. Bell's guidance. During his post-graduate training period, he served as pathologist at the Minneapolis General Hospital. His Ph.D. thesis concerned a study of splenic disorders; this study undoubtedly had a significant influence in Dr. Watson's lifelong interest in hematological disorders. In 1928, as a young pathologist, Dr. Watson went to Minot, North Dakota, to a newly-formed clinic. There he had the unusual roles of pathologist, director of laboratories, and also assistant to the internist in the group, Dr. Paul H. Rowe. At that clinic and the immediately adjacent hospital, he served the dual role as resident physician for many hospital patients as well as assuming the responsibility for the duties of hospital pathologist and supervisor of the general laboratory work. The close association with Paul Rowe was an important factor in channeling Dr. Watson's interests into the field of clinical medicine. While at Minot, North Dakota, Dr. Watson continued the studies on urobilinogen excretion that he had started while a pathologist at the Minneapolis General Hospital. In order to further his academic and scientific career, Dr. Watson returned to Minneapolis in 1930 and took advanced courses in organic chemistry. He then went to Munich, Germany, to work in the laboratory of Hans Fischer. While in Fischer's laboratory, Dr. Watson accomplished the crystallization of stercobilin* from an extract of feces. Chemists had long been defeated in an attempt to isolate this substance. This accomplishment further increased Dr. Watson's keen interest in a basic study of the bile pigments as derivatives of hemoglobin catabolism. He stayed a second year in Munich as a National Research Council fellow and, while continuing to work in Fischer's laboratory, managed to find time to attend the medical clinics of the famed Friedrich von Mueller. Thus he continued his interest in clinical medicine while pursuing basic investigations in the field of biochemistry.

---

*See Test Your Word Score Page 271.

By 1932, Dr. C. J. Watson had firmly set himself on a career in academic medicine. His initial post on returning to Minneapolis was that of an assistant resident in Medicine at the Minneapolis General Hospital and later at the University Hospital. He continued both basic and clinical studies in the field of bile pigment-porphyrin chemistry while working as a resident at these two hospitals. Somehow he managed to find time to continue work in the laboratory. Without the aid of a great deal of expensive equipment, and certainly without the "benefit" of large research grants, he continued to make significant observations and contributions in his chosen scientific field. It was at this time that he succeeded in crystallizing a urobilin* from human urine and demonstrating that it was identical with the original crystalline stercobilin that could be obtained from feces. His intense interest in the compounds of stercobilin continued throughout the years. In his laboratories he and his students eventually described at least three different members of the urobilin group of substances, the dextrorotatory,* levorotatory* and inactive forms.

In 1932, while still a resident in Medicine at the General Hospital, Dr. Watson was given the responsibility of organizing a course in clinical chemistry and microscopy for the medical students. This he did with great energy and skill. His stimulating presentations of the application of laboratory procedures to the solution of clinical problems had a profound influence on many students. I, for one, was influenced in my decision to pursue a career in internal medicine, by this stimulating young lecturer who presented his material to the junior medical school class in Todd Amphitheatre. The skill of this young physician as a teacher and his accomplishments as an investigator did not escape the attention of the medical school administrators. His rise in the academic ranks was steady, comparatively rapid and certainly well deserved. In 1936, while an Associate Professor of Medicine, Dr. Watson was named as the Director of the Division of Internal Medicine. At that time, the Department of Internal Medicine was under the direction of Dr. J. C. McKinley. Four years later, while continuing as the director in the division, Dr. Watson was named Professor of Medicine, and in 1942 became Chairman of the Department, a post which he holds to this day. At the time that Dr. Watson became a Professor of Medicine and Chairman of the Department of Medicine, the Department was small. The entire staff had no problem assembling in his office, one formerly occupied by Hilding Berglund and located on the second floor of the University Hospital in the Todd Wing just behind the deep X-ray department. Shortly after the outbreak of World War II, Dr. Watson once again found himself participating in a dual professional role, this time as a visiting professor of medicine to the University of Chicago, while continuing his duties in Minneapolis. The Chicago work involved the Manhattan Project. As the Associate Director of the Health Division of the so-called metallurgical laboratory, Dr. Watson would spend two weeks in Minneapolis, two weeks in Chicago. This went on month after month throughout the war. None of us in the department knew the nature of his work and it was

---

Continued

not till the awesome news of Hiroshima was flashed to the world that we became aware of the type of wartime endeavor he had been engaged in. Following the conclusion of World War II, came an era in which many professors of medicine began to take on responsibilities beyond those of their own departments. More and more national committees, conferences and related matters arose to claim the time of prominent men in academic medicine. Cecil Watson did not escape from these added responsibilities; throughout the subsequent years he served on many professional and governmental committees and boards. For a number of years he was the recorder for the Association of American Physicians, later counsellor and, in the year 1960-61, acted as president. He served as a member of the Committee on Medicine and Surgery in the National Research Council as well as on the medical Fellowship Board of the Council. He was an active member of the American Board of Internal Medicine for some years and devoted a great deal of time to the development of their systems of examination. He continues to be an active participating member of such organizations as the Minnesota Society of Internal Medicine, the Central Society for Clinical Research, the American Society for Clinical Investigation and has served in each as the president. In 1959 he was honored by election to the National Academy of Sciences, a distinction not often accorded to investigators in the field of clinical medicine.

Dr. Watson's keen interest in and knowledge of diseases of the liver has long been recognized. From 1942 to 1948, he served as Chairman of the Liver Injury Conference, a series of meetings sponsored by the Josiah Macy, Jr. Foundation. Thereafter he continued as a member of the conference for the next five years. He was asked to assume the position of Director of the Commission on Liver Disease of the United States Armed Forces Epidemiological Board when the commission was founded in 1948. The writer served as Dr. Watson's deputy director and continued to function in this capacity until 1954 when the Commission was reorganized under a different sponsorship.

As the national and international reputation of Dr. Watson grew, more and more demands were made upon his time, including many requests to deliver lectures. One of the earliest and certainly one of the most outstanding requests came when he was asked to deliver the Harvey lecture in New York in 1948. Other outstanding lectureships in which he has participated include the Chester M. Jones lecture at the Massachusetts General Hospital, the George R. Minot lecture for the American Medical Association, and the John Phillips lecture of the American College of Physicians in 1957. Dr. Watson has been honorary lecturer at a number of medical schools in this country as well as abroad. He has been named honorary professor at San Marcos University in Lima, Peru, and was given the same distinction at the University of Chile in Santiago. On a return visit to Chile in 1960, he received the Order of Merit from the Republic of Chile. More recently, in 1962, he received an honorary M.D. degree from the Johannes Gutenburg University in Mainz, Germany.

Throughout these many years of devoted service to the University of Minnesota Medical School, Dr. Watson has achieved the admiration and warm friendship of an untold number of students, interns, residents and faculty associates who have pursued their studies under his guidance or have worked with him.

As an expression of the esteem that his former students and past and present colleagues hold for Dr. Cecil J. Watson, a Recognition Day was held on September 25, 1961. A scientific program with a presentation of original papers by a number of his former students and associates was held in the Mayo Memorial Auditorium. That evening a dinner was held in his honor. The speaker was Dr. William Castle, Professor of Medicine at Harvard University.

The University of Minnesota School of Medicine is fortunate to have had as distinguished an individual as Dr. C. J. Watson to lead one of the major departments of the Medical School from a very small beginning to the current large and productive department that now exists. Dr. Watson's unbounded enthusiasm for clinical and basic investigation continues. Despite the many and arduous duties that confront him, he finds time to counsel and advise those who have the good fortune to work under his guidance. His unselfish devotion to the welfare of the Medical School of the University of Minnesota is recognized and deeply appreciated by the entire faculty and student body.

Moses as Sanitarian

It corresponds to the reality in both the actual and chronological point of view to consider the books of Moses as the foundation of sanitary science. The more we have learned about sanitation in the prophylaxis of disease and in the prevention of contagion in the modern time, the more have we come to appreciate highly the teachings of these old times on such subjects. Moses made a masterly exposition of the knowledge necessary to prevent contagious disease when he laid down the rules with regard to leprosy, first as to careful differentiation, then as to isolation, and finally as to disinfection after it had come to be sure that cure had taken place. The great lawgiver could insist emphatically that the keeping of the laws of God not only was good for a man's soul but also for his body.

Baas: Outlines of the History of Medicine.

The Superior Man — Confucius (551 to 479 B.C.)

The superior man understands what is right. The inferior man understands what will sell.

The superior man is liberal toward other's opinions but does not completely agree with them; the inferior man completely agrees with others' opinions but is not liberal toward them.

I don't like spinach, and I'm glad I don't, because if I liked it I'd eat it, and I'd just hate it. — Clarence Darrow

The Doctor and Literature

(Continued from page 254).

our anger is satiated. Our victim is ruined and heart broken. And our virtue goes quietly to sleep for seven more years."

Dr. Polidori, accompanied Lord Byron as that unhappy genius dragged through Europe the pageant of his bleeding heart. The faithful doctor tried vainly to curb the excesses of the great romantic poet.

William Shakespeare

William Shakespeare's patron, the Earl of Southampton, withdrew his favor and financial support when he stole the playwright's light-of-love, Mistress Mary Fitton, the Dark Lady of the Sonnets.

Shakespeare bemoans his lot in the opening lines of Sonnet Twenty-nine:

"When in disgrace in fortune and
men's eyes
I all alone bewail my outcast state
and trouble deaf heaven with my
bootless cries
And look upon myself and curse my
fate."

In Romeo and Juliet, Shakespeare gives a rather unattractive description of an apothecary and his shop.

"I do remember an apothecary
Which late I noted in tattered weeds,
with overwhelming brows
culling of simples.
Meagre were his looks,
Sharp misery had worn him to the bone
And in his needy shop a tortoise hung
An alligator stuffed and other skins of
ill shaped fishes;
And about his shelves a beggarly account
of empty boxes
Green earthen pots and old cakes of roses
were thinly scattered to make up a show."

The Apothecary, often known as a herbalist, because he sold love philtres to the credulous, reluctantly sells Romeo a mortal drug.

"Put this in any liquid thing you will and drink
it off
And if you had the strength of twenty men it
would dispatch you straight
My poverty, but not my will consents."

Reverend Edward Keanan
St. Paul, Minnesota

(To be continued next month)

Medieval medicine taught that the soul resided in the liver which secreted vapours and humors.

A hot and dry man was melancholy: melan meaning black, choly signifying bile. A melancholy man suffered from a superfluity of black bile.

A hot and moist man was sanguine and cheerful.

A cold and moist man was phlegmatic or torpid.

The Anatomy of Melancholy by Robert Burton

Curbstone Consultation

Flexor Tendons of Little Finger

QUESTION: Ten months ago both flexor tendons of the little finger were severed and resutured. The finger remains in straight extension with no sign of motion in the middle and distal joints. The extended finger is constantly in the way. What treatment would you recommend at this late stage wherein motion remains only in the metacarpophalangeal joint?

ANSWER: If both flexor tendons were severed and there is a great deal of binding and scarring down, then it may well be that arthrodesis in a semi-flexed position, so that the fingers no longer point in an extended position, would be the best solution. In some individuals in whom the flexibility of the hand is extremely important, and there is no possibility of regaining flexibility in the little finger, the ray resection has been utilized, rather than trying to do any form of reconstruction.

Your question poses the possibility that motion remains only in the metacarpal phalangeal joint, which does bring up the ray resection as the only solution that might be practical in some instances. However, there still is the possibility that a patient would rather try the fixed flexed position before this amputation procedure is done, which can always be performed at a later time.

University of Miami School of Medicine

Aerosolized Content of Hair Sprays

QUESTION: What dangers exist in the use of hair sprays through inhalation of the aerosolized contents?

ANSWER: The pulmonary changes which have been attributed to inhalation of such sprays have varied from sarcoid-like granulomata to diffuse interstitial fibrosis. The basic agent in hair sprays is an inert substance, polyvinylpyrroliodine (PVP). Experimental work in animals with this chemical has not confirmed the findings said to occur in humans as a result of exposure to this substance. Human studies involving women who were users and nonusers of hairspray showed no difference between the two groups as measured by mid-expiratory flow rates. Observations and studies over longer periods of time will be required before an accurate judgment can be rendered as to effects that might result in persons using hairsprays.

The Viewing Box

This 50-year-old white male presented to Hennepin County General Hospital in acute respiratory distress. His symptoms were those of an upper respiratory infection. He had a history of alcoholism and for the past week had been living in a boxcar. On admission the patient appeared acutely ill and in moderate respiratory distress. He had hemoptysis and a white blood count of 4300, of which 79% were PMNs. Of interest is that six months before this admission his chest x-ray was normal.

The admission chest film (Figure 1) is typical of this disease. Notice especially the massive consolidation with bulging fissures due to a volume increase of the affected lobe. Also characteristic is the clear, sharp border of the infiltrate.

What is your diagnosis? (See next page.)

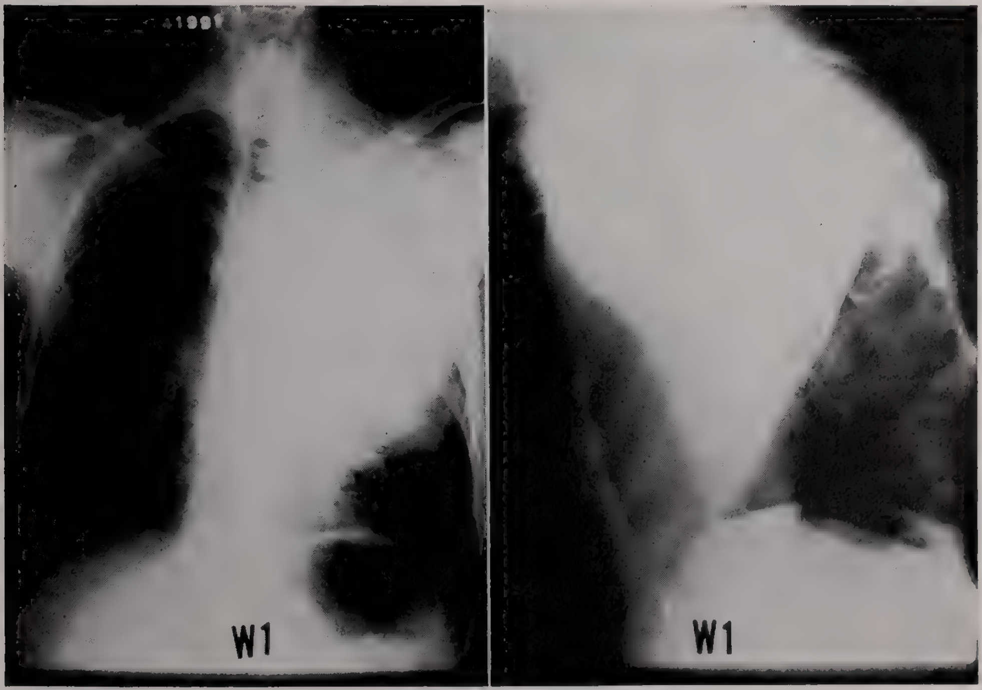

Fig. 1

Diagnosis: Friedlander's (Klebsiella) Pneumonia.

Friedlander's pneumonia, in the acute form, is most prevalent in debilitated individuals. It is most common in males, especially over the age of forty, and there is a high correlation with alcoholism. It is most common in the apical and posterior segments of the upper lobe, and favors the right lung.[3] Friedlander's pneumonia is reported to be responsible for ½ per cent to 1 per cent of all pneumonias in the adult.[1] The etiologic agent, Klebsiella pneumoniae, normally occurs in the respiratory tract from 5 per cent to 25 per cent.[3]

Clinical features of the disease include: acute onset in a toxic individual, thick red sputum, high fever, and pleuritic pain. Leukopenia is common in most infections.

The radiographic picture may resemble other pneumonias. Early abscess formation and cavitation are not uncommon.[4] Because of this, and since the upper lobes are most frequently affected, the differentiation from a tuberculous pneumonia may be difficult.[5] More characteristic are the bulging fissures with a massive consolidation, the border of which is sharp and easily seen.

The patient presented had bacteriologic confirmation of Friedlander's pneumonia. His course was one of rapid deterioration, and in spite of intensive therapy, he died six hours after admission.

Incantations

Closely akin to the power of numbers is that of words. Pliny once says on an incantation employed to avert hailstorms that he would not dare in seriousness to insert its words, although Cato in his work on agriculture prescribed a similar formula of meaningless words for the cure of fractured limbs. But Pliny does not object to the repetition of incantations or prayers if the words spoken have some meaning. In one case where a poultice is to be applied to an inflammatory tumor, Pliny says that persons of experience regard it as very important that the poultice be put on by a naked virgin and that both she and the patient be fasting. Touching the sufferer with the back of her hand she is to say, "Apollo forbids a disease to increase which a naked virgin restrains." Then, withdrawing her hand, she is to repeat the same words thrice and to join with the patient in spitting on the ground each time. Indeed, in another passage Pliny states that it is the universal custom in medicine to spit three times with incantations.*

Fracture–Trauma Conference

Massive Hemorrhage from Pelvic Fractures

It is apparent from clinical experience and a recent autopsy study at Ancker Hospital that massive hemorrhage from fractures of the pelvis does occur and can have lethal consequences.[1] In some instances bleeding is so rapid that blood replacement alone is inadequate. Ligation of hypogastric arteries as a means of treating otherwise uncontrollable hemorrhage from pelvic fractures was first suggested in 1963 by Miller[2] who used it in five patients. Seavers and associates[3] subsequently reported their experience with four patients in whom this treatment had been utilized. This report is a review of our recent experience with patients with fractures of the pelvis and an analysis of the role played by hemorrhage. Results of hypogastric artery ligation in four patients are also given.

Material and Method of Study

The charts and x-rays of all patients admitted to Ancker Hospital with fractures of the pelvis from January 1, 1959, to September 1, 1964, were reviewed. Age, sex, duration of life after admission to the receiving room and mode of injury were recorded. The total number of blood transfusions expressed in units of 500 ml. was tabulated for each patient. The type of pelvic fracture was determined from the x-rays and categorized according to the classification proposed by Key and Conwell[4] and utilized by Milam and Miyakawa[5] in their analysis of urinary tract complication of pelvic fractures.

Type I — Fractures Without a Break in the Pelvic Ring

These include fractures of the wing of the ilium, a single pubic or ischial ramus, fracture of the anterior superior iliac spine, the ischial tuberosity, sacrum or coccyx.

Type II — Fractures with a Single Break in the Pelvic Ring

These include fractures of both rami of one side, separation of the pubic symphysis or separation of the sacroiliac joint.

Type III — Fractures with a Double Break in the Pelvic Ring

Included here are double vertical fractures and severe multiple fractures.

Continued

Type IV — Fractures of the Acetabulum

Using this classification, the mortality rate and percentage of patients with significant blood loss have been determined according to the type of fracture.

Associated Injuries

The nature and extent of associated injuries were tabulated according to criteria employed by Slatis.[6] Thus, lacerations, contusions, and abrasions were excluded from consideration.

Head Injury

Fracture of skull; contusions and lacerations of brain substance; epidural, subdural or subarachnoid hemorrhage;

Chest Injury

Multiple rib fractures, hemothorax, pneumothorax, contusion or laceration of thoracic viscera, and rupture of diaphragm;

Abdominal Injury

Laceration or rupture of parenchymatous organs or rupture of gastrointestinal canal;

Genitourinary Injury

Rupture or laceration of kidney, ureter, bladder, or urethra;

Spinal Injury

Fracture and dislocation of spine with or without injury of spinal cord;

Lower Extremity Injury

Fracture or major vessel injury; and

Upper Extremity Injury

Fracture or major vessel injury.

An attempt was made to assign a primary cause of death in patients who died. This was facilitated by a high autopsy rate (34 of 37 deaths). All deaths directly or indirectly caused by fracture of the pelvis were noted, and this group was further subdivided into those patients who succumbed primarily to blood loss and those who died of other sequelae of the pelvic injury. Both the over-all mortality rate and that due to pelvic fracture were related to mode of injury, type of fracture, and blood loss. Patients with significant blood loss are arbitrarily defined as those who received or should have received blood transfusions.

Results

A total of 196 patients with fracture of the pelvis were admitted to Ancker Hospital during the period studied. Sex distribution was essentially equal with 96 males and 100 females. Distribution by age was fairly uniform from the second through the ninth decades but with only five patients in the first decade and four in the tenth. Average age was 51.4 years with an age range of four to 92 and a median age of 54.

Causative Factors

Traffic accidents accounted for the injury in two thirds of the cases. There were 78 pedestrians struck by cars, approximately 40% of the total. Fifty-two patients or 27% were auto occupants. There were 48 patients or 24% who sustained fracture of the pelvis in falls of a minor nature. This mode of injury involved an older age group as reflected in an average age of 73.1 years and a median age of 79.5. Eighteen patients were injured in a variety of mishaps such as crushing accidents and defenestration of two to four stories.

Mortality Factors

There were 37 patients who died, an over-all mortality rate of 19.4%. Fifteen or 7.7% died primarily from the pelvic injury. Of these, 11 were pedestrians, two auto occupants and two victims of falls.

Severity of Injury

The duration of survival of 37 patients who died reflects the severity of the injuries sustained and the need for vigorous therapy from the outset. Twelve or 32% of deaths occurred within four hours of admission and 22 patients or 59% died within 48 hours. Only one patient died before some treatment could be instituted. Of the 15 patients dying primarily of pelvic fracture, seven or 47% died within four hours and 10 or 67% within 48 hours of admission.

Type of fracture and mortality rate were studied. There were 54 patients with Type I fracture and five deaths, a mortality rate of 9%. Eighty patients had Type II fracture; of these 12 or 15% died. There were 45 patients with Type III fractures, 17 or 38% of whom died. Three of 17 patients with fractures of the acetabulum died, a mortality rate of 18%; none of these deaths was primarily due to the pelvic fracture. In contrast, nine of the 45 patients or 20% with Type III fractures died from their pelvic injuries, as did five of 80 with Type II fractures, a mortality rate of 6%. Only one patient of 54 with Type I fracture died of the pelvic injury, a mortality rate of 2%.

Blood Loss

Significant blood loss, as previously defined, occurred in 77 of the 196 patients. In 63 of these patients blood loss was thought to be primarily from the pelvic fracture (Table 1). Therefore 63 patients, or 32% of the 196 patients, bled significantly from their pelvic injuries. Of these 63 patients, 19 died, a mortality rate of 30%. Of 24 patients receiving more than five units of blood, 13 died, a mortality rate of 54%. In contrast, 119 patients not requiring blood transfusion had a mortality rate of only 8%.

TABLE I
Hemorrhage from Pelvic Fracture

Patients Requiring Transfusion:	63 of 196 = 32%
Mortality Rate of Patients	
Requiring Transfusion:	19 of 63 = 30%
Requiring 1 or 2 Units:	1 of 13 = 8%
Requiring 5 or More Units:	13 of 24 = 54%
Requiring No Transfusion:	9 of 119 = 8%

Continued

In general, the more severe the pelvic fracture the greater was the blood loss. Forty-five patients with Type III pelvic fracture received 335 units of blood or 7.4 units per person, while patients with Type I, II and IV fractures received approximately one unit each (Table 2). Similarly, the percentage of patients receiving blood transfusion was significantly higher in patients with Type III fracture. Thirty of 45 patients with Type III fractures (67%) were given at least one unit of blood, while 15 of 54 (28%) with Type I, 24 of 80 (30%) with Type II, and four of 17 patients (24%) with Type IV fracture required transfusion.

TABLE 2
Type of Fracture and Blood Loss

Type	No. Patients	Total No. Units	Units per Patient
I	54	75	1.4
II	80	87	1.1
III	45	335	7.4
IV	17	16	0.9

Associated Injuries

Associated injuries as defined occurred in 96 patients. The most common associated injury was fracture of the lower extremity which occurred in 54 patients, 18 of whom died; there were no large vessel injuries among these. Chest injuries occurred in 33 patients, 15 of whom succumbed. The upper extremity was fractured in 21 patients, seven of whom died. Fourteen of 16 patients with severe head injuries expired. Fifteen patients had rupture of the bladder or urethra, of whom eight died. Abdominal viscera were injured in 13 patients, seven having ruptured bowel or mesentery, six ruptured spleens, and four minor liver lacerations. There were 10 deaths among these 13 patients, but none was primarily attributed to the abdominal injury. Spinal injury was an associated injury in eight patients, only one of whom died. There were 31 deaths in these 96 patients with associated injury, a mortality rate of 32%. This is in marked contrast to 100 patients with pelvic fracture but no associated injury where the mortality rate was only 6%.

Deaths Attributed to Pelvic Fracture

Closer scrutiny of the 15 patients dying primarily of their pelvic fractures revealed the following data. The average age of these 15 patients at death was 62.8 years as compared to 49.0 years for the survivors. Cause of death in these 15 patients was hemorrhage from the pelvic fracture in nine, fat embolism in two, arteriosclerotic heart disease in two, and severe ileus with electrolyte imbalance in two. Of the nine patients whose deaths were from pelvic hemorrhage, eight were pedestrians and one an auto occupant. Six of the nine died within four hours of admission to the receiving room and eight of the nine died within 24 hours, the ninth dying on the fourth day after admission. Six had Type III pelvic fractures, while three had Type II, and there were none with Type I or IV fractures. Additional injuries were present in eight of the nine, two having a single associated injury and six having two associated injuries. Two of these patients underwent operation, one for repair of the bladder, the other an exploratory laparotomy only; neither had ligation of the hypogastric artery.

Ligation of Hypogastric Artery

During the past year we have had an opportunity to utilize hypogastric artery ligation in four patients with severe hemorrhage from pelvic fractures. The case histories of these patients are reported in detail elsewhere.[7] All four were initially in profound shock and in only one patient was the blood pressure stabilized with initial blood replacement; the other patients had persistent or recurrent hypotension despite continuous blood transfusions. At operation all were found to have massive retroperitoneal hematomas secondary to their pelvic fractures. No effort was made to locate the exact site of hemorrhage other than to verify the integrity of the larger blood vessels. In three patients ligation of the hypogastric artery on the side of the pelvic trauma resulted in abrupt control of the blood loss, while in the fourth patient both hypogastric arteries were ligated before there was a dramatic decrease in the bleeding. Postoperatively there was no recurrence of shock or hypotension in any of the patients. Three patients survived while the fourth died seven days later of fat embolism. Autopsy in that patient revealed that no further hemorrhage had occurred following ligation of the arteries.

Discussion

Although many of the data presented here simply reflect the increasing risk of hemorrhage and death from increasingly severe trauma, some are of definite significance regarding hemorrhage and death from pelvic fractures. Pedestrians have a significantly higher mortality rate from pelvic hemorrhage than do auto occupants or persons injured in falls. This is correlated with the fact that pedestrians sustain more extensive fracture of the pelvis on the average than do patients injured in other ways. This study substantiates the logical hypothesis that the more extensive the pelvic fracture, the greater is the risk of hemorrhage and death from hemorrhage. It also suggests that we can predict with some accuracy from the type of pelvic fracture which patient will be likely to bleed massively. In addition, this study stresses the not-so-well appreciated fact that there is a very high incidence of blood loss requiring transfusion in patients with pelvic fractures, regardless of the extent of the fracture.

Deaths attributed to hemorrhage from pelvic fracture have been shown to occur shortly after admission in nearly all patients. This reflects the fact that hemorrhage can be very rapid and is most likely arterial in such instances. Therefore, if treatment is to be effective, blood must be replaced early and vigorously, and ligation of the hypogastric arteries must be considered.

As Miller[2] has shown, massive hemorrhage in many cases originates from ruptured branches of the hypogastric arteries, these branches lying in close proximty to the pelvis. To find and ligate these ruptured branches at operation is exceedingly difficult, if not impossible, because of their anatomic location and the extensive hematoma which is always present. Ligation of the hypogastric arteries, on the other hand, is a simple procedure. We feel that any patient with pelvic fracture whose blood pressure cannot be restored rapidly with blood replacement and maintained with

Continued

only a few more transfusions, and in whom other cause of hemorrhage has been ruled out, should be considered for hypogastric artery ligation.

Summary

Experience with 196 patients with pelvic fractures over a recent five-year period reveals the over-all mortality rate to be 19.4%. Seven and seven-tenths per cent died primarily from the pelvic injury.

Significant hemorrhage from the pelvic fracture was found in one third of the patients and was by far the leading cause of early death due to pelvic fracture.

Experience with hypogastric artery ligation in four patients suggests this technique is of value in controlling massive hemorrhage from pelvic fractures.

Tumor Conference

Squamous Cell Carcinoma of the Anus

Squamous cell carcinoma of the anus accounts for about four per cent of all anorectal malignancies.[1,2] It must be differentiated from such benign lesions as thrombosed hemorrhoids, condylomata, chancre, nonspecific ulcers or tuberculosis. Malignant lesions of the anus also include malignant melanoma, lymphoma, carcinoid and anorectal adenocarcinoma. Epidermoid cancers arising just above the pectinate line tend to have a more varied histologic structure and a greater malignant potential than those arising from the anal margin.[3]

Aside from local invasion, the tumor spread follows the lymphatic drainage of the anal canal. It involves the lateral pelvic nodes via the inferior and middle hemorrhoidal plexus and the preaortic nodes through the superior hemorrhoidal plexus. Portal and systemic hematogenous dissemination occurs by this route. Metastatic spread to the inguinal lymph nodes follows either the hypogastric pathway or directly through perineal lymphatics. Squamous cell carcinomas of the anus, which are located distal to the pectinate line, are more likely to metastasize to inguinal nodes than those which originate at or above the pectinate line.

Case Report

A 72-year-old white veteran was admitted on July 29, 1963, with the chief complaint of "painful hemorrhoids" of three months' duration. The patient was known to have had large hemorrhoids for at least twenty years. Since the onset of pain, he had also noted some bleeding from the anus and had become aware of a growing mass.

He was well nourished and there were no abnormal abdominal findings. In addition to several skin tags, an edematous mass with surface maceration was seen around the posterior anus. Anoscopy revealed immobile internal hemorrhoids. The prostate was smooth and moderately enlarged. The lobulated posterior anal mass did not involve the pectinate line. The inguinal lymph nodes felt normal. A punch biopsy of the anal growth revealed infiltrating squamous cell carcinoma.

On September 26, 1963, an abdominoperineal resection with wide perineal and pelvic margins was performed. The preaortic, common iliac, external iliac and hypogastric nodes were removed en bloc. Eleven normal lymph nodes were identified and no metastases were found. The tumor measured 6 cm. x 4 cm. x 2.5 cm. and originated distal to the pectinate line. The nearest line of perineal resection was 3 cm. from tumor tissue (Figure 1). The postoperative course was stormy and complicated by thrombo-

Continued

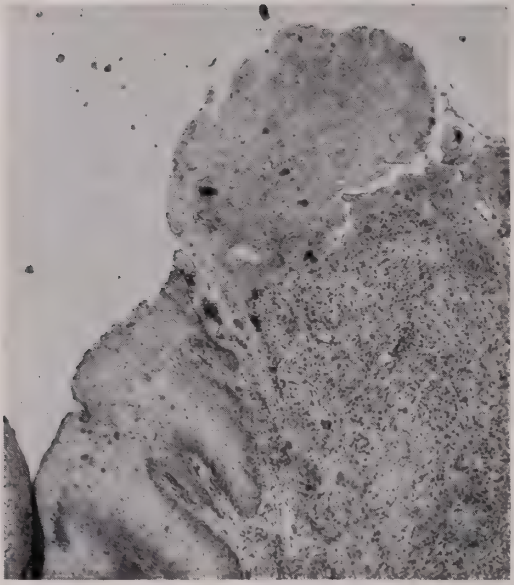

Fig. 1 — Specimen of abdominoperineal resection. The anal skin gives way to an exophytic, infiltrating, well differentiated squamous cell carcinoma.

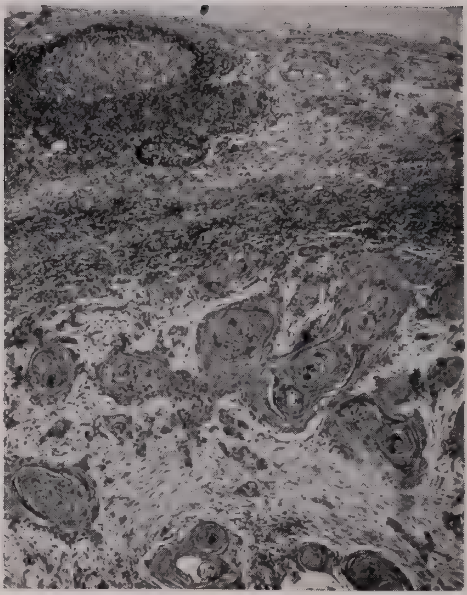

Fig. 2 — Inguinal lymph node, largely replaced by squamous cell carcinoma.

phlebitis in the left leg. When this subsided, a persistent enlarged left inguinal lymph node was noted. Excision biopsy showed squamous cell carcinoma within a lymph node.

On March 4, 1964, a left radical groin dissection was performed, using the technique of Byron et al.[4] Thirty-four lymph nodes were identified. Squamous cell carcinoma metastases were found in nodes of the lower triangle of Scarpa (Figure 2) and in subcutaneous nodes below the inguinal ligament. The recovery was delayed by wound dehiscence and by marked lymphedema of the left leg. The patient was discharged on June 5, 1964, and has been followed at regular intervals. At this time, two years after resection of the primary tumor, there is no demonstrable recurrence of cancer and the lymphedema of the left leg has largely subsided.

Comment

The management of squamous cell carcinoma of the anus is controversial. Local excision or treatment by irradiation has been disappointing.[1,6] An en-bloc resection of the tumor and its primary areas of lymphatic drainage necessitates an abdominoperineal resection and bilateral radical groin dissection in continuity with the tumor. In view of the increased mortality and high morbidity with this radical procedure a "watch and wait" attitude now prevails.[2] The abdominoperineal resection is followed by groin resection only when inguinal metastases have appeared. Sedgwick and Wainstein[5] oppose this approach and state: "When large positive inguinal nodes are present, groin dissection adds nothing to the survival rate and is contraindicated." Stearns[6] found that only 6% of patients with anal carcinoma would have benefited from prophylactic groin dissection. However, in his group of thirteen patients who had been treated with abdominoperineal resection and with groin dissection after an interval, five were well two to six years after resection of the primary tumor. Our patient had a stormy and prolonged recovery from an abdominoperineal resection. When inguinal metastases became apparent after a four months' interval, a radical groin resection was performed. This major procedure was also followed by grave complications. The elderly man may not have survived both operations had they been performed simultaneously.

Neurological Conference

Management of a Convulsive Disorder*

Student Doctor Guy O'Grady

This 38-year-old married woman has had seizures since 18 years of age. Her first seizure occurred on the same day that she began a new job and consisted of a sudden loss of consciousness, resulting in her falling down several stairs. There was no aura, and the patient was told that she lay motionless during the period of unconsciousness. Since that time she has had perhaps 20 to 30 seizures, sometimes with an interval of one to two years between episodes. More recently, however, she has noted an increase in the frequency of the attacks and has had five seizures in the last six months. They are particularly prone to occur during menstrual periods or when she is excited; for instance, she had a seizure on the day after Christmas, while entertaining some of her friends. This attack was not preceded by an aura. Her sister described the patient as suddenly falling to the floor with clonic movements of both legs, and then lying quietly for about five to 10 minutes before regaining consciousness. She could give no further description except that the patient did not bite her tongue, nor was she incontinent of urine or feces during the episode. The patient commented that she often did not feel well for several days after a seizure. During a typical postictal** state, she experiences weakness, headache and marked depression. She has taken phenobarbital 30 mg. q.i.d. after each seizure but usually discontinues the medication within a few months.

Past History

The patient had pulmonary tuberculosis in 1951, at which time she was hospitalized for 17 months and treated with streptomycin and para-amino salicylic acid. Chest films have showed no change since the time of dis-

---

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held every Wednesday from 1:00 to 3:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward De Foe in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Held on Wednesday, April 15, 1965, 4 p.m.

**See Test Your Word Score Page 271.

Continued

charge from the sanatorium, and a recent gastric washing revealed no tubercle bacilli.

The patient was married in 1963 and became pregnant in January, 1964. Preeclampsia developed and she was placed on two medications to combat her increasing hypertension. No seizures occurred during the pregnancy, but in late September the patient delivered a stillborn. Consequently, she has been very concerned about the advisability of future pregnancies.

There is a strong history for gout among the patient's relatives; three of her mother's 10 siblings had clinical gout.

Laboratory Data

Physical examination of the patient was entirely normal. The laboratory data revealed a normal blood count and urinalysis, a two-hour postprandial blood sugar of 96 mg.%, a serum uric acid of 5.8 mg.%, and a normal electrocardiogram. The waking electroencephalogram showed bursts of 4 to 5/second spike and wave complexes superimposed on a mildly abnormal background only during hyperventilation. It was felt that the record suggested a centrencephalic convulsive disorder.

The patient was seen subsequently in Neurology Clinic where a thorough neurological examination confirmed the normal physical examination. Dilantin 100 mg. b.i.d. and phenobarbital 100 mg. h.s. were recommended to be taken indefinitely. It was felt at that time that the patient probably had grand-mal seizures.

Dr. Robert Soll*

Dr. Wilson, is there anything you can add about her seizure history?

Dr. Louis Wilson**

Yes, the patient's older sister has petit-mal attacks, characterized by short epidoses of amnesia. I think they are under control now, however.

Dr. Soll

Frequently, as patients grow older, their petit-mal attacks may be replaced by major motor seizures.

The Patient Enters the Conference Room

Dr. Soll

Would you describe to us how you feel just before a seizure occurs?

Patient

I don't think I actually know, except for the last attack I had. I think I probably felt it coming on, so I started for the bedroom. When it occurred, I was between the kitchen and dining room door. I felt a strangeness possibly.

Dr. Soll

How do you feel after you have had a spell?

Patient

I know that just minutes after I have had one, I am talking, but I remain groggy and also depressed for the rest of the day. I think I am just plain disgusted that I had another attack.

---

*Pediatrician and Moderator, University of Minnesota Hospitals.

**Referring physician.

Dr. Soll

How do you feel about having another child?

Patient

I think I would like to have one, of course, but no one can be certain of having a well baby.

Dr. Soll

Since we have given you more medication this past month than you have had for a number of years, have you felt any different?

Patient

Yes, I am much more drowsy. I could sleep 15 hours out of 24.

Dr. Soll

It will probably be some time before we really know how effective this medication will be in preventing your seizures, since they have been relatively infrequent in the past.

Dr. Richard Magraw*

I am not sure that I understand why you decided to check into your seizures now.

Patient

I asked Dr. Wilson about it, and he thought it would be a good idea to be certain there wasn't any brain damage or a brain tumor. After I had one of the seizures at home I decided to find out if anything more could be done.

Dr. Magraw

Had there been any change in the seizures?

Patient

No.

Dr. Magraw

Why did you want to do something about this now rather than last year or next year? What was the last straw that made you decide?

Patient

I just felt that probably there was something else that could be done so I wouldn't be having the seizures any more. I had been taking phenobarbital and I felt that maybe there might be another drug that I could be taking. Of course, I had just had the baby recently.

Dr. Magraw

Did you think that there might be some connection between the two?

---

*Director, Comprehensive Clinic.

Continued

Patient

Yes.

Dr. John Brantner*

Did your last seizure occur shortly after your first visit to the University?

Patient

The very last one that I had was at that time, yes.

Dr. Soll

Have you ever noticed any relation between your seizures and your periods?

Patient

Yes, the seizures usually occur at the time of my period. That is why I thought it may have had something to do with my pregnancy.

Patient Leaves the Room

Dr. Magraw

There is an old question and one that should always be asked in medicine: Why does the patient complain? She has had seizures for 20 years, so why should she inquire more about them now. In this instance, it clearly appears that she is relating the control of her seizures with her physical fitness and her likelihood of having a successful pregnancy.

Dr. Brantner

I asked about the date of her last seizure because several people have suggested that one of her prolonged postictal symptoms was a mild depression. I have the results of her Multiphasic. Although I did not notice any evidence of depression in the patient myself, it did appear in the Multiphasic. She had a seizure on March 16. The Multiphasic which was taken 14 days later revealed a mild depression and anxiety; otherwise, it was normal. It did not indicate significant hypochondriacal concern, but rather only a reasonably normal number of physical complaints for a patient. She is an intelligent woman, with an IQ of 120 (the lower range of the superior level). Testing her was a little difficult, as it sometimes is with some intelligent people who don't understand why they are asked to answer simple questions and to perform easy tasks. On visual motor coordination tests, she shows no signs of cerebral dysfunction. The Porteus Maze was a little lower than might be expected with her level of intelligence. This might be related to the EEG findings, or more likely, it shows that she is a person who can be flustered easily; for example, she made one minor mistake that she should not have made, after which her performance deteriorated considerably. She repeated the mistake a second time and became even more flustered.

Miss Helen Kretchmer**

I interviewed the patient during her second clinic visit. She was very responsive to everyone with whom she talked. She and her husband were married in August, 1963. He had been married previously and has two children, a boy 17 years old and a girl aged seven. The patient seems happy with her marriage and enjoys the children. Her only pregnancy terminated in a stillbirth, but she would still like to have a child of her own.

---

*Assistant professor, clinical psychology, University of Minnesota Hospitals.

**Supervisor and assistant professor of social service, University of Minnesota Hospitals.

After graduation from high school the patient had one year of business college before beginning work in the office of a physician. She remained there for 17 years, until the doctor retired. The patient's husband is a carpenter for a construction company, earning approximately $180 a week before deductions.

Although the patient's sister, who has seizures, is doing well on medication, the patient continues to worry about her own condition. She is anxious to have another child, but the possibility of toxemia or a recurrence of her lung condition has caused her much concern. She also thinks there may be an increased likelihood of seizures in her child. The prospect of having a child is painful for her to discuss, but I believe she would benefit by consultation with an obstetrician regarding future pregnancies.

She is also concerned over advice that she should not drive until complete control of her seizures is attained. The 17-year-old boy has never seemed willing to drive although he passed his driver's training; so it is difficult for her to manage when her husband is away.

The evaluation here has been anxiety-provoking for the patient and she hopes to be referred back to Dr. Wilson for care as soon as possible. She does not like to come to the city alone and seems anxious because her husband is not here with her. The patient's sister said that she was overly fearful even about members of her family knowing that she has seizures; however, the sister feels that she has carried this to extremes.

The patient is paying for medical care here on a per-diem or reduced-fee basis. There are no local agencies active.

The patient has a good relationship with her physician, Dr. Wilson, and he has given her supportive help through previous illnesses. With adequate seizure control, her anxieties may be reduced, but she will need more help in understanding her condition and deciding whether to go through another pregnancy, which she both desires and fears.

Dr. Soll

I would like to ask Dr. Charles Tietz to comment on the patient's obstetrical history and then give us his recommendation regarding any future pregnancies for the patient.

Dr. Charles Tietz*

I have several questions that I would first like to ask. When did she develop preeclampsia?

Dr. Louis Wilson

It was after the pregnancy was approximately 20 weeks. She had albuminuria.

Dr. Tietz

Did she seem to respond to treatment fairly well?

---

*Medical fellow, obstetrics and gynecology, University of Minnesota Hospitals.

Continued

Dr. Wilson

Yes, her pressure was as high as 160/110, and at the time of her last office visit just before she delivered, it was 148/72. It took several weeks to return to normal.

Dr. Tietz

I think the problem that a woman of this age presents is whether toxemia is superimposed upon chronic hypertensive disease or whether she is developing arteriosclerosis. The history that has been given suggests that she simply had preeclampsia, though this is difficult to establish, really, because we have had fetal losses when the maternal blood pressure was in the range of 130/90 as well as with blood pressures in the range of 170/120.

I see no reason why she shouldn't have another pregnancy, particularly if she is normotensive at the present time. I would lean toward watching her more closely than I would if she had a previously normal pregnancy. Usually patients who will not do well are those who are chronically hypertensive, having a pressure in the vicinity of 170/110. They will either abort very early or have early second trimester losses. It is very possible that her stillbirth was not due to preeclampsia. She lost the baby at about 37 weeks.

Dr. Wilson

She hadn't felt any movement for four days before delivery and the fetal heart tone was not present then.

Dr. Tietz

The cause of a stillbirth may go without explanation in as high as 80% of the cases. Occasionally there are obvious causes such as diabetes, erythroblastosis or severe toxemia. Nevertheless, the reason she lost the baby may not have been due to the blood pressure at all. She doesn't have much of a reproductive career remaining, but if she wants a child, one could watch her closely and probably even deliver her early, particularly if she showed signs of not responding well to therapy. An unexplained stillbirth is the usual situation. Most patients with this kind of story do well in their next pregnancy. Of course, this patient's age is against her, plus the fact that she has had preeclampsia. I would say the chance of her getting recurrent toxemia with this next pregnancy would probably be somewhere in the neighborhood of two to three times greater than an ordinary person. The fact that she didn't have any seizures during her pregnancy is in her favor.. About 30% of women who have seizures and become pregnant will have an increase in seizure frequency. Another 30% will have no change at all and the remaining ones will improve.

Dr. Soll

Hormonal changes can aggravate the seizure condition because of salt and water retention. The usual anticonvulsant medications such as barbiturates and dilantin are usually well tolerated during pregnancy.

Dr. Tietz

Other than the gingival changes in the mothers, which are infrequent, we haven't found any serious side effects to the usual anticonvulsant medication. I suppose that her next pregnancy would be extremely important if there is such a thing as a premium baby.

Dr. Wilson

I am not certain that she really had wanted to get pregnant initially, but she was very disappointed that she didn't have this child. Once she was pregnant she felt wonderful.

Dr. Soll

Approximately 80% of all patients with seizures can achieve virtually complete control. Here at the University it is quite likely that we see mostly problem cases in which control hasn't been achieved; consequently, many of our patients do comprise a relatively small selected group who continue to have seizures.

The goal for which we strive in using anticonvulsant medications is optimum control of seizures with the least amount of sedation. Drowsiness is probably one of the most common side effects, and this would be expected, since most anticonvulsants are depressant in nature.

Barbiturates comprise probably one of the largest groups of anticonvulsant medications and have virtually replaced the bromides which now are seldom used except in very unusual circumstances. The main area of usefulness of the barbiturates is for treatment of grand-mal and psychomotor seizures. Phenobarbital is one of the most commonly used in this group, being the safest as well as the cheapest.

Mephobarbital or mebaral is simply a methylation of the basic phenobarbital molecule. Much of it undergoes demethylation in the body to phenobarbital, accounting for at least part of its anticonvulsant activity. On a weight basis, it is not as potent as phenobarbital, since 60 to 100 mg. of phenobarbital would be equivalent to 200 mg. of mephobarbital in suppressing seizures. One interesting aspect concerning the use of barbiturates is that they are fairly long-acting; consequently, a single or twice daily dose produces almost as good seizure control as multiple divided daily doses. Often this feature can be used to advantage by administering the barbiturate at bed time when drowsiness is a desirable side effect. The patient is then relatively more alert during the day.

Mysoline, the chemical name of which is primidone, is very closely related structurally to the barbiturates but is not a true barbituric acid, since it does not have the acid radical. This drug is also commonly used in treating grand-mal and psychomotor seizures. When first starting a patient on mysoline, it is important to remember to start with very small doses in the range of 50 mg. two or three times daily. Subsequently the dose may be gradually increased to 250 mg. three times daily. This will minimize the likelihood of vertigo, drowsiness or gastric upset.

Diphenylhydantoin sodium, commonly known as dilantin, has been used since 1938 and ranks next to the barbiturates in being one of our most potent drugs. It is a very good drug from the standpoint that it produces minimal sedation with probably as great an anticonvulsant potency as any medication we have available. Using a combination of dilantin with one of the barbiturates such as phenobarbital or mebaral is a very common

Continued

practice since they seem to supplement each other in controlling seizures. Approximately one third of patients who take dilantin for a long period of time may develop hyperplasia of the gingivae. This is not a serious complication, however, and is almost never a good reason for discontinuing the drug, as good dental hygiene will usually control this problem, and an occasional patient who develops a severe hyperplastic reaction can be treated by the dental surgeon if necessary. There are two commercial preparations in which dilantin is combined together with a barbiturate. Mebroin is a tablet containing both mebaral and dilantin. Phelantin is a capsule containing phenobarbital, dilantin and desoxyephedrine. In general these are more expensive in this form but have the advantage of reducing the number of pills a patient must take each day.

For petit-mal seizures, tridione is one of the most commonly used anticonvulsants. This type of seizure is much more difficult to control as a rule than most other seizures, and tridione will control only about one third to one half of patients with petit-mal seizures. If tridione fails to help, paradione may be substituted. Besides the diones there is also another group of drugs used in the treatment of petit-mal seizures, called the succinimides, which include Celontin, Milontin and a more recent addition, Zarontin. Tridione is used in doses of 300 to 600 mg. four times daily. Again one should start out with smaller doses, gradually increasing until the optimum dose is achieved.

Some drugs can be categorized into an adjunctive group of anticonvulsants. The carbonic anhydrase inhibitor, Diamox, may have an anticonvulsant activity by virtue of its diuretic activity as well as its ability to induce metabolic acidosis. This latter may be somewhat similar to the metabolic acidosis produced by a ketogenic diet commonly used at one time. Another medication, Elipten, has been used as a supplemental medication to the standard anticonvulsants particularly in the treatment of refractory seizures. The mode of action of this preparation is unknown. Side effects are very few; a rash may occur in some cases, although this usually clears spontaneously within a few days. Finally, there is the group of amphetamine drugs which are used chiefly to counteract sedation produced by the barbiturates or other anticonvulsants.

Significant toxicities resulting from the anticonvulsant drugs appear infrequently. Rashes are probably one of the most common side effects shared by almost all of these medications including the hydantoins and barbiturates. One of the first hydantoin drugs which actually preceded dilantin was nirvanol. Its use was associated with a very high incidence of fever, lymphadenopathy, and various types of blood dyscrasias. Mesantoin, which is simply a methylation of nirvanol, produces many of the same complications and is not often used clinically. Although in the same group of drugs, dilantin fortunately has an extremely low incidence of similar side effects.. Phenurone is sometimes used for psychomotor seizures; but this is a very dangerous drug which should be employed only in those instances when there is no other possible medication available to control the seizures.

Dr. Richard Magraw

This patient really has had very few seizures. Much of her difficulty may be that she has a pretty damaged concept of herself. She is the kind of person who is driven by the feeling of not being worth very much, and this is the attitude that has made her such an efficient office nurse. Over the years, these people are prone to have recurrent feelings of depression. She has already told us some of the things that bring this on, for example, her seizures, having had tuberculosis, the loss of a child, etc. When she advances into the involutional period, she will be even more inclined to this type of reaction.

Dr. Soll

We can strive to achieve complete seizure control within the next year or two. This may help her to increase confidence in herself. The regimen of dilantin and phenobarbital that she is now receiving should be well tolerated, and it is very unlikely that these medications would interfere with any future pregnancy.

Dr. Magraw

I feel that the lesion which needs even greater attention is her poor "self" concept. I am reminded of a young girl who came to the University ostensibly to have her esotropia treated. This was her complaint, but when asked what really bothered her, she said "The kids at school call me a 'cross-eyed' bean pole." Similarly, obtaining control of her seizures should be helpful for the patient, but she will continue to be vulnerable to anything that comes along which might indicate a flaw in the weave, so to speak.

This is a classic example of a patient who presents to you a very obvious handle by saying, "Here's my problem, seizures." However, it is much more complex than that. There is a Norse legend about Loki,* a Norse god, challenging Thor to lift a certain cat. Thor strained to pick the cat up, but found that it was really the disguised head of a mythical serpent which had twined itself about the earth three times. As a result he had been trying to lift the whole globe and not just the cat.

I mention this story because problems often come to us in this way. We may try to avoid becoming involved by interpreting the patient's complaint in the most literal sense. Yet it is better for the patient, from the standpoint of his recovery, to understand the whole problem and not only the superficial difficulties.

Discussing these various feelings which she has concerning herself with these individuals, particularly Dr. Wilson, would be beneficial and can serve to reinforce her "self" concept.

Conclusions of the Conference

1. Control of the patient's seizures should be obtained by appropriate regulation of her anticonvulsant medications.
2. The patient should be reassured that her convulsive disorder very likely will not adversely affect a future pregnancy.
3. Although there is a possibility of recurrent toxemia with another pregnancy, it is less than with her first pregnancy and should not deter her from having a child.
4. The patient should be helped in improving her own "self concept" through discussions, primarily with her family physician.

Robert Soll, M.D.
University of Minnesota

*See page 304.

Continued

Participating in the conference were Dr. John Brantner, Assistant Professor, Clinical Psychology; Miss Helen Kretchmer, Supervisor and Assistant Professor of Social Service; Student Doctor Guy O'Grady; Dr. Charles A. Tietz, Medical Fellow Obstetrics & Gynecology; Dr. Richard Magraw, Director, Comprehensive Clinic; Dr. Louis Wilson, referring physician and Dr. Robert W. Soll, Neurologist.

On Lifting a Cat*

The Scandinavian Eddas treat us to some stirring tales of the old Norse gods: not only their heroic triumphs but their humiliating defeats as well. It is precisely because these pagan gods were represented as neither omnipotent nor invincible that we moderns, like the early Norse whose fertile and flamboyant imagination produced them, can relate warmly to them. Like ourselves they were humanly fallible.

One of these gods, of the Aesir** membership, was the valiant and redoubtable Thor (Thursday is his namesake), who always carried a mighty hammer — and seldom failed to use it upon the slightest pretext — or even with no provocation at all.

On one of Thor's numerous jaunts to alien territories to show off his extraordinary strength and skill, he proceeded to Giantland (Utgard) where Loki† reigned. Knowing Thor's vanity and presumptuousness and thinking to show him up before the assembled Giants in the banquet hall, Utgard-Loki challenged him to demonstrate his prowess by lifting a large gray cat which suddenly leaped into the middle of the hall, apparently from nowhere. "Nothing to it!" thought Thor as he bent and seized the cat beneath its stomach. But though the cat's back arched upward with each tremendous endeavor by Thor to lift the animal, only one paw was finally raised slightly off the floor on Thor's last and most prodigious effort. On Thor's departure Utgard-Loki confided to his discomfited guest that the mere cat had not been a cat at all but Midgard, the formidable World Serpent, who in old Norse cosmography encircled the earth with its tail in its mouth. And furthermore, added Utgard-Loki: when the cat's paw had been slightly raised off the floor, all the Giants had been aghast and had trembled as Midgard's mouth and tail momentarily separated under the strain, thereby jeopardizing the solidity and cohesiveness of the very globe itself.

**Aesir, the pantheon of Norse gods, headed by Odin.

†Not to be confused with Loki, spirit of evil and mischief, the 'enfant terrible' of the Aesir.

Progress Note

The patient was asked if he had passed his specimen. He replied that he hoped so — the nurse was doing the examination but she hadn't told him whether or not he passed.

I don't know who my grandfather was; I am much more concerned to know what his grandson will be. — Abraham Lincoln

Child Psychiatry

Behavior Problems and Cerebral Dysfunction in Children[*]

In the course of a day's work the physician in general practice will probably see three or four patients who would be designated "behavior problems." These may be minor in scale and intensity when compared to the caseload of a child guidance clinic. They are rarely minor to the parents and may actually be creating havoc in the household or schoolroom. It is a well recognized fact, however, that the nature and severity of the symptoms are no index as to the nature and severity of the problem behind them.

This report is concerned with the small number of such behavior problems which originate in the failure of the parents or teacher to recognize, understand and accept the fact that a subtle neurological handicap in the patient may be a contributing factor. It is often the physician's responsibility to evaluate such behavior problems, to diagnose the organic defect, if there be any, and to provide counsel that will increase the parents' understanding of their child, and hopefully thus relieve some of the attendant tensions in his home or school environment. It is these tensions, really, that bedevil him.

Silver[1] states, "The behavior of a child with brain damage is not only a function of the biologic damage itself, but it is also dependent upon the child's psychological defense patterns and upon the environmental forces acting upon him. The biologic defect in turn, however, influences the child's psychologic structure, its maturation, its gratifications, and defense patterns, so that we are in effect dealing with a reciprocal interaction of biological, psychological, and environmental forces, all of which need evaluation in understanding the child's behavior."

Experience has demonstrated that children with obvious neurological handicaps such as palsy, convulsions, severe retardation or degeneration rarely manifest the perplexing behavior problems with which this paper is primarily concerned. Bender[2] states, ". . . when a child with a recognized handicap becomes a problem of sufficient severity to come to the hospital, there has usually been some other more significant social or emotional factor than the specific handicap."

The cerebral dysfunction, which is the concern of this paper, is so minimal it escapes recognition. Too often, if unrecognized, it may become a significant factor in the genesis of behavior problems.

It is still a common misconception that occult cerebral dysfunction will cause abnormal behavior. It is often inferred that brain injury may result in objectionable behavior in the child and delinquent behavior in the adoles-

---

[*] *Editor's Note:* Dr. A. S. Anderson, a pediatrician, has prepared a very interesting paper on a difficult and troublesome problem for most of us. It is presented in two parts. The first section defines and illustrates the problem. The second will deal with diagnostic procedures, treatment and prevention.

Continued

cent. The same concept provides basis for the idea that objectionable and delinquent behavior is possibly inevitable in certain instances of brain injury. Time and experience are proving this concept untrue. In my own practice I have made the following observations, which in my mind tend to refute the theory in question.

1. Severe head injuries resulting in permanent neurological sequelae without any permanent behavior problem.

2. Hitherto unrecognized stigmata of organic brain damage in children with ideal behavior.

3. The dramatic appearance of behavior problems when parents gain understanding and are enabled to accept the handicap of their brain-injured child.

4. The persistent post-brain infection or head-injury behavior problem limited to those children in whom such a problem would be expected even in health, because of emotional stresses within the family.

Concerning a series of 86 children with head injury behavior problems Bender[2] stated that in all but two who had posttraumatic epilepsy no one organic defect or any combination of them was the sole reason for the behavior disorder or personality maladjustment.

In a discussion of his own paper, Neurology and Psychiatry in Childhood Posttraumatic and Postencephalitic Syndromes, Blau[3] said, "Although I stated quite definitely in previous reports that there is a distinct posttraumatic and postencephalitic syndrome, I have learned differently. I am now trying to retract some of the things I wrote previously. As I studied these children more carefully and worked with the parents, the picture became more clearly psychiatric and one that should not be dismissed as an incurable organic condition."

The causes of cerebral dysfunction itself are really outside the scope of this paper, but because paranatal difficulties are so often cited by physicians and parents as significant in the etiology of behavior problems, I feel justified in pointing out here that the expensive, arduous, anticipatory longitudinal studies necessary to establish the organic factors in behavior problems are yet to be reported. Pasamanick[4] has done a large community epidemiological study in which it would appear that prematurity, toxemia and hypertensive disease of pregnancy are more significant in the origin of behavior problems than prolonged labors or difficult or operative deliveries. Keith, Norval and Hunt[5], at the Mayo Clinic, in a study which followed 4,464 children from one to seven years, found 1.3% had neurological lesions, but difficulties during delivery had little to do with the abnormalities in the infants who lived. No evidence was found that prolonged labor, asphyxia or delayed respiration caused any neurologic defect in the children who lived.

To demonstrate the genesis of the particular group of behavior problems which are the concern of this paper it will be helpful to consider six case reports, in brief. They have been selected because (1) they illustrate dysfunction in each of six areas of cerebral function and (2) they clearly demonstrate behavior problems whose cause is lack of recognition of the neurological functional handicap deriving from a subtle organic brain defect.

Case Reports

Neuromuscular Dysfunction

The only son of an ambitious executive was eight and one-half years old and in third grade. His problems were fearfulness, poor school achievement, failure to complete his classwork and an unusual number of minor ailments which required medical attention. The significant abnormalities found on physical examination were poor coordination, hyperactive knee jerks in the prone position, and allergic rhinitis. In order to develop "aggressiveness, courage and competitiveness" in this passive youngster the father had inaugurated a program of increasingly intensive athletic drills. Though under excellent executive management this program was failing to make either an aggressive athlete or courageous defender. By means of the examination and the interview following, the well-meaning father was helped to recognize his son's coordination handicap and the fact that the athletic drilling had not only frustrated but had also further incapacitated the boy. This insight opened the way to further insights regarding healthy parent-child relationships and their importance to emotional growth. As a result this boy's multiple symptoms, which were his reaction to pressure and misunderstanding, disappeared almost over night, though his coordination defect is still demonstrable.

This case study presents a defect in neuromuscular function which, until recognized by the father, contributed in part to a parent-child misunderstanding which in turn contributed to school, behavior and medical problems.

Intellect Dysfunction

This child was six and one-half years old when her mother consulted the physician. According to her mother, the child was chronically unhappy, subject to frequent severe illnesses, and achieving poorly at school. Hospital reports of the child's past illnesses, however, failed to confirm the mother's reports regarding their seriousness or severity. Physical examination revealed incoordination and hyperreflexia. At this point it was strongly suspected that the child was brain-injured and had handicaps in other areas as well. Psychological testing revealed an I.Q. of 80, but only minimal disturbance in the area of perception. An I.Q. of 80 is borderline for special class placement in school, but since she was not achieving in the regular classroom, she was placed in a special class. With relatively little interpretation the parents came to understand and accept the child's limitations, and consistently each time she has been seen during the past three years, the mother has reported her to be outgoing, happy, and no longer subject to frequent or severe illnesses.

This case demonstrates that recognition and understanding and acceptance of the child's neurological limits (especially in the area of intellect) created a new emotional environment for her, one in which she could be happy (despite her continuing handicap) and medically healthy.

Perception Dysfunction

An only child was brought to the physician at the age of nine because of his disturbing classroom behavior. The teachers had also observed problems in achievement, socialization and coordination. Physical examination revealed abnormalities in coordination and tendon reflexes. Psychological testing revealed an I.Q. of 93, accompanied by severe perceptual abnormalities. The electroencephalogram tracing was markedly abnormal. Conferences with parents and teachers proved ineffective. Rapport with the father was obviously unsatisfactory, and he overtly manifested this by becoming a chronic credit problem. Intensive trials of several drugs brought about no significant or permanent improvement in the patient's behavior. A psychiatric referral was not acceptable to the parents. Later, an opportunity to observe the child vacationing with several other children presented itself. In this setting he demonstrated no neuromuscular or socialization problems. The following year he was expelled from school because of unacceptable behavior. At this time the parents secured a tutor for him. She acquired keen insights into the boy's problems and was successful in her special teaching program. She developed excellent rapport with the parents and through her they themselves gained insight and understanding of their son's achievement and behavior problems. In retrospect the parents also give credit to the book, *The Other Child*, by Lewis, Strauss, and Lehtinen.[6] Lewis is a father who had a

Continued

child with a similar brain injury problem, and Strauss, a teacher by profession, has been a pioneer in the education of brain-injured children.

Several years have passed now since this boy's parents had their significant experience with his tutor. Though the boy continues to have school achievement problems, his behavior has not indicated need for further professional help. Incidentally, the parents' credit problem evaporated, and as they gained in understanding and acceptance of this child their need for constant pediatric help diminished.

This is obviously a complex problem, but for the sake of simplification we can say that some of the stress associated with school was basic to the child's social behavior, since in a vacation setting his behavior was relaxed and unobjectionable. Even his school behavior improved when his parents and teachers came to understand and accept his specific handicap.

Impulse Activity

A girl came to the physician as a seven-year-old child known to have severe neuromuscular and perceptual and impulse dysfunction. She had done well in a special school for children with perceptual handicap. The parents came for help in making plans for her to attend a boarding school. They were distressed in particular over her agitated, destructive behavior at home during and immediately following a period during which the parents were away on a vacation. During this holiday the woman who was staying with the girl brought her to the physician with symptoms of fever and respiratory disease. No infection was found. At this time the physician wasn't insightful enough to question the woman concerning the real problem, the child's behavior. The physician did record in the chart the observation that the child's temporary guardian demonstrated very little understanding of her and seemed inept in her management. Aside from making this note, the physician reassured the guardian the child was free of infectious disease.

To prevent rampant hyperkinetic behavior in obviously brain-injured children with excessive impulse activity there is a need for support in the form of kind, understanding, firm and consistent discipline, and protection from excessive emotional stimuli. Discipline and protection were obviously lacking while the parents were on vacation. When the mother gained insight into the situation the behavior problem disappeared. It was not necessary to place the child in a boarding school.

Neurosensory Defects

The patient in this case study is a seven-year-old girl known to the physician since she was age one. She has rarely needed pediatric attention, and as well as could be determined from the records, her family relationships should have been excellent. Her teacher, however, called the mother's attention to the fact she was out of contact in the classroom and was falling behind in reading. A correctable visual defect was discovered, and glasses seem permanently to have cured her behavior and learning problems.

Distortions in Sensorium

A ten-year-old girl had a chronic respiratory allergy problem. At the age of four years she had one grand-mal convulsion and following this paroxysms of unconsciousness. When she was ten years old her teacher noted that she was under-achieving in school and her behavior was characterized as "not being with it." A provisional diagnosis of petit-mal epilepsy was made and Tridione was added to the drug regimen. She responded dramatically; her school achievement and behavior problems disappeared and her need for pediatric visits was limited to those periodic checks of blood and urine necessary in Tridione therapy.

This case demonstrates the elimination of the behavior problem characterized as "not being with it" when specific therapy was introduced; when the patient's behavior returned to normal the minor medical problems disappeared.

In each of these six patients an abnormality in behavior was one of the major presenting symptoms. The specific problems were unwarranted fearfulness, generalized unhappiness, unacceptable school behavior, agitated, destructive activity, and daydreaming in the classroom. When the cerebral dysfunction in each case was recognized, understood and accepted by the adults in the child's environment the behavior problems disappeared. The problem of under-achievement in school was relieved in four cases and the need for an excessive number of pediatric visits was notably lessened in three. That the cerebral handicap was the result of an organic neurologic defect was confirmed by its persistence even after the creation of a different emotional environment at home and at school had made it possible for the child's offensive behavior to be resolved.

Medical Schooling of the Past

It may be interesting to turn back the pages of history a few hundred years, to see what some of the really old boys had to study and stomach. Blasius Gronewalt began his medical schooling at the University of Leipzig in 1506 and in later years the books that he had used were collected by the library of Kreuzschule at Leipzig. There were only two medical books in the collection. One was the tractates and expositions of Petrus Hispanicus, who was a practising physician during the late thirteenth century, having studied at Montpellier and Paris. This book concerned treatment and dietetics and was based a great deal upon the sayings and teachings of Hippocrates (460-370 B.C.) and Galen (130-200 A.D.). The other medical book was the "Pandectae Medicinae" by Matthaeus Sylvaticas, which was a reference text of pathology and pharmacology. All of the other books were of a nonmedical nature and included texts on metaphysics, astrology, politics, ethics, economics, famous editions of Aristotle and the works of Cicero, Caesar, Plutarch, Valerius Maximus, Ovid, Livy, and Quintilian. In addition, the poor fellow had to study Greek!

Taking an ECG?

Complete the clinical picture
with **a heart sound recording**

... made on your 500 VISO when you take the ECG

Increase your knowledge of cardiac condition with the valuable *additional* information provided by heart *sound* recordings. With this new Sanborn Heart Sound Amplifier clipped to the front of your 500 VISO* you can immediately obtain clear, sharply defined, graphic records — which identify the *location, intensity* and *duration* of the sounds and murmurs within the cardiac cycle. Even in the presence of complex arrythmias, marked tachycardias and other conditions which may complicate or prevent accurate auscultation by stethoscope alone, a definitive record of diagnostic quality can be obtained with this new instrument. Frequency cutoffs of 50, 100, 250 and 500 cps can be switch-selected to separate murmurs which might otherwise be masked by other heart sounds. As an electronic stethoscope, all sounds from 50 to 2000 cps can be heard at normal or amplified levels.

This precise Sanborn amplifier has convenient controls for recording the ECG, PCG, or ECG superimposed on the PCG . . . Cutoff Frequency . . . Audiophone Volume . . . and Sensitivity. Complete with contact microphone, cable and Audiophone (for use as an electronic stethoscope), Model 1506A is $450 f.o.b. Waltham, Mass. (continental U.S.). For more information, use the convenient coupon below. Sanborn Division, Hewlett-Packard Company, Waltham, Mass. 02154. In Europe, Hewlett-Packard S.A., 54 Route des Acacias, Geneva.

**or almost any other ECG with a 50 mm/sec. chart speed.*

Surgical Seminar

Lymphedema of the Upper Extremity

Presented as a seminar sponsored by members of the faculty of the Mayo Graduate School of Medicine.

LYMPHEDEMA WAS observed as long ago as 1500 B.C. in India where elephantiasis apparently occurred commonly enough to warrant marriage restrictions.[1] Hippocrates had experience with various swellings of the extremities and treated them by scarification. In spite of this early beginning, until recently not much has been known about the etiology, pathology, and pathogenesis of lymphedema. The work of Kinmonth and associates[2] with direct lymphangiography has provided some information on the etiology of the edematous limb by pinpointing some of the structural defects that exist in the lymphatic systems of these patients.

Basic Considerations

Definition of Terms

Lymphedema is the specific type of edema due to accumulation of lymph in the soft tissues. It has been defined[3] as the edema which results from lymphatic obstruction, has certain microscopic qualities, and differs clinically from venous edema.

Anatomy of the Lymph Vessels

The human integument has a rich lymphatic supply, consisting of a superficial and a deep capillary plexus. The superficial plexus forms a freely anastomosing network in the papillary layer of the skin; its vessels are composed of a single endothelial layer and have no valves. This layer is connected to a deeper layer between the dermis and the subcutaneous tissue. These latter channels are larger, may have smooth muscle in their walls, and have valves which give them a beaded appearance.

The lymphatic network of the hand consists of dorsal and palmar plexuses which converge and course up the volar surface of the forearm as ulnar and radial channels, ultimately terminating in the axillary lymph nodes.[4] A deeper system follows the large vessels of the arm and also empties into the axillary lymph nodes with or without intervention of the deep cubital lymph nodes. The superficial and deep systems are connected at the elbow.

A lateral channel, which courses with the cephalic vein in the deltopectoral groove before entering the subclavicular or supraclavicular lymph nodes, is an important collateral after radical mastectomy.

Physiology

The endothelium of the lymphatic vessels is more permeable than that of the blood capillaries. The main function of the lymphatic system is to return large molecules, such as proteins, to the blood. The passage of fluid from the blood capillaries to the tissues is described by Starling's hypothesis. Thus increased capillary hydrostatic pressure, decreased capillary osmotic pressure, and increased capillary permeability may cause edema.

The most important factors governing lymphatic flow are the movement of muscles and the competency of lymphatic valves. Webb and Starzl[5] pointed out that the pulsations of large arteries may be important. The circulation of lymph is rapid; Blocker and coworkers[6] have shown that circulation from the foot to the thoracic duct in humans in a

Continued

supine position under general anesthesia requires about three minutes.

Lymph contains fibrinogen, prothrombin, lymphocytes, erythrocytes, urea, creatinine, sugar, chlorides, and amino acids. Kinmonth and Taylor,[7] in studying patients with congenital lymphedema of the legs, found that the protein content of the lymph was increased, the average being 2.5 gm./100 ml. (normal[8] for human skin lymph, 0.69 gm./ 100 ml.) and that the rate of absorption of lymph was considerably slower than in the normal extremity.

Regeneration of lymphatic vessels is rapid unless excess scar formation and infection supervene. Reichert[9] showed that regeneration begins as early as the fourth day and that by the eighth day regeneration of vessels across a scar is physiologically complete.

Pathogenesis

Regardless of the cause of lymphedema, a consistent sequence of events occurs. Stagnation of lymph in the vessels causes gradual dilatation, the valves becoming incompetent if the lymphedema persists long enough. The protein content of the tissues increases and, since lymph is an excellent medium for fibroblastic growth, fibrosis ensues which further increases lymphatic blockage. Infection is also likely to occur in this protein-rich transudate, with resultant thrombosis and blockage of lymphatic vessels.

Lymphedema may be clinically divided into inflammatory and noninflammatory types (Table).

Classification of Lymphedema*

- I. Noninflammatory
  - A. Primary
    - 1. Lymphedema praecox
    - 2. Congenital lymphedema
      - a. Hereditary or familial (Milroy's disease)
      - b. Simple
  - B. Secondary
    - 1. Malignant occlusion
    - 2. Surgical removal of lymph nodes
    - 3. Pressure
    - 4. Roentgen and radium therapy
- II. Inflammatory
  - A. Primary (single or recurrent acute and chronic)
  - B. Secondary (single or recurrent acute and chronic)
    - 1. Venous insufficiency
    - 2. Trichophytosis
    - 3. Systemic disease
    - 4. Filariasis
    - 5. Local tissue injury or inflammation

Etiology

Noninflammatory Primary Lymphedema

Primary noninflammatory or idiopathic lymphedema includes the congenital types (hereditary or simple) and lymphedema praecox.

Although involvement of the upper extremity by congenital lymphedema is very rare, cases have been reported.[10,11] In the simple type, one family member is involved; while in the hereditary type a number of blood relatives are affected. Clinically there is diffuse swelling involving part or all of the extremity but without pain or ulceration. The swelling, usually noted at birth, is firm but subsides greatly on elevation of the extremity. The cause is unknown, although heredity probably is a factor.

Lymphedema praecox usually develops during the first or second decade of life and is rare after 40 years of age. Swelling generally begins distally in the foot and slowly progresses proximally. Females predominate in a ratio of about 10:1.[12] In a recent study of 122 patients with lymphedema praecox, Schirger and associates[12] found that the upper extremities were involved in five patients and the genitalia in two.

The cause of lymphedema praecox is unknown. The predominant incidence in women, with onset during adolescence and worsening during menstruation, indicates that the reproductive system may be related to the problem.

Kinmonth and associates[13] studied 87 cases of idiopathic lymphedema (12 of 107 cases were congenital) by lymphangiography. Hypoplasia was found in 55% and aplasia in 14%, the latter occurring more frequently in the congenital and in the more severe cases. Dilated or varicose lymph channels were found in 24% and were also more frequent in the congenital group. A familial tendency and a 14% incidence of other associated congenital anomalies lend support to the theory of congenital lymphatic maldevelopment as a cause of idiopathic edema.

Pathologically, the changes in lymphedema praecox are similar to, although not as marked as, those in congenital lymphedema.[12] The subcutaneous tissues are thickened, and the skin is rough. Microscopically, dilated lymphatic spaces lined by endothelial cells and hyperkeratosis may be seen. The epidermis undulates and often atrophies over the edematous projections of dermis. Lymphedematous tissue of long duration generally shows fibrotic change, disruption of collagen fibers, and fragmentation of elastic fibers of the dermis with attenuation of superficial lymph vessels by perilymphatic inflammatory reaction, interstitial edema, and fibrosis.

Noninflammatory Secondary Lymphedema

This type of lymphedema may be caused by lymph nodal occlusion by lymphoma, surgical removal of lymph nodes, extrinsic pressure on lymph vessels, or roentgen or radium therapy. It is characterized by rather sudden onset of swelling and by more rapid progression than in idiopathic lymphedema. Lymphangiographic studies in these patients may reveal dilated or tortuous channels and accentuation of the subcutaneous pattern of small lymph vessels, known as dermal reflex. Kinmonth and associates[13] stated that the lymphatic vessels rarely show more than the smallest degree of dilatation in obstructive lymphedema but that the dermal backflow is always striking.

In many patients, lymphedema develops after radiation therapy subsequent to surgical ablation of lymph structures; whether the swelling is due to radiation fibrosis or to the surgical procedure is uncertain. Irradiation obliterates lymph sinuses and closes channels, but the beneficial effects of 50 to 80 r of x-radiation in acute obstructive lymphangitis or lymphadenitis cannot be denied. West[14] reported excellent results in treating postmastectomy lymphedema with doses of 100 r and stated that x-radiation relieved vascular spasm, permitting better drainage.

Whether cobalt-60 teletherapy will decrease postoperative lymphedema is currently unknown.

Lymphedema After Radical Mastectomy

The swelling of the arm that occurs after radical mastectomy is the most common type of lymphedema of the upper extremity. Unfortunately, the pain and disfiguration of the lymphedematous arm postoperatively may be as psychologically traumatic to the patient as the initial shock of the operation.

The reported incidences of lymphedema after radical mastectomy are extremely variable because of lack of standard measurements and because of differences in definition of what constitutes a swollen extremity. Some degree of swelling exists in approximately 50% of patients and is severe in five to 30%.

Stillwell[15] listed three types of swelling that occur following radical mastectomy: acute transient, transient acute painful, and persistent painless edemas developing at various intervals postoperatively. Theories of causation are numerous but are based primarily on venous or lymphatic obstruction.

INFECTION

Halsted[16] thought that lymphatic and venous obstruction contributed to postoperative swelling but that infection, often subclinical, was actually the cause of the swelling. Because infection led to axillary cicatrization which caused or accentuated the swelling, Halsted believed that reduction in axillary dead space was important in reducing the incidence of infection. The strongest argument in favor of skin grafting is that it reduces dead space. Villasor and Lewison[17] found no correlation between skin grafting and postmastectomy lymphedema but thought that infection was the most important single factor causing or increasing the lymphedema. Daland[18] stressed the importance of avoiding infection and emphasized that the skin incision for radical mastectomy should not be on the arm.

VENOUS OBSTRUCTION

Russo and co-workers[19] measured venous pressure and performed venography on 15 patients preoperatively and postoperatively; they demonstrated complete axillary vein

Continued

block in five and moderate distortion of the venous lumen in six. They concluded that venous changes were due to extensive dissection around the axillary vein, causing phlebitis or thrombosis with subsequent increased venous pressure and stasis.

In 1960 Smedal and Evans[20] suggested that postmastectomy edema of the arm was due to thrombophlebitis of the axillary vein with concomitant inflammatory lymphatic obstruction in the perivascular sheath. They reported clinical evidence of thrombophlebitis in 85% of their cases and venographic evidence of phlebitis in a high percentage. Extensiveness of the surgical procedure and presence of axillary metastasis were the two most important predisposing factors to thrombophlebitis. If thrombophlebitis is the cause of postmastectomy lymphedema of the arm, the possibility of prophylactic anticoagulant treatment arises.

However, Schorr and associates[21] found no correlation between the state of the axillary vein, as seen on the venogram, and arm swelling; but on venography of 18 patients without arm swelling postoperatively, the cephalic vein was seen in 16. Thus, preservation of the cephalic vein may be important in preventing postmastectomy lymphedema. They commented on the difficulties in interpreting venograms, pointing out that axillary vein compression on the venogram may be physiologic due to clavicular compression of the vein as it enters the subclavian vein.

MacDonald and Osman[22] advocated axillary vein resection, with preservation of the cephalic vein, as part of the axillary dissection because it permitted more complete dissection and did not increase the incidence of postoperative swelling. They thought that arm swelling was due to lymphatic obstruction caused by perivenous lymphangitis, which was eliminated by resection of these channels when the axillary vein was resected.

OTHER FACTORS

Thrombophlebitis with resultant venous and arterial vasospasms has led to treatment of postmastectomy lymphedema by stellate ganglion block. However, the effect of vasospasm in the development of lymphedema is not clear.

There are many opinions concerning the role of irradiation in postmastectomy lymphedema. Some consider the development of radiodermatitis to be important, not the use of irradiation *per se*. In a large series of cases studied by statistical analysis, Treves[23] found that patients treated by x-ray, especially preoperatively, had a higher incidence of arm swelling. However, x-ray treatment alone was not associated with the higher incidence of swelling.

Obesity seems to be the only predisposing factor on which various authors agree. It is generally true that obese patients have a higher incidence of lymphedema, and their lymphedema is of greater severity. This is perhaps related to the fact that obese patients are more likely to have skin flap necrosis and secondary infection; it also may be explained by the necessity of removing more fatty tissue and, consequently, more lymphatic vessels.

Treves[23] summarized the possible causes for postmastectomy lymphedema as follows:

"It appears that lymphedema following radical mastectomy cannot be attributed to any solitary factor, but a combination of several factors may operate in any given case. Probably the most frequent cause is interference with the return of lymph because of ablation of the profunda lymphatics with the nodes of the axilla. Interference may be due directly to the axillary dissection or to cicatrization following infection or fibrosis following roentgen-ray therapy. Angulation of the vein, interfering with both venous return and return of lymph from vessels in the wall of the vein, and reflex spasm of the axillary vein must likewise be assessed as bearing directly on the problem."

Prophylactic measures to prevent lymphedema after radical mastectomy should include avoidance of infection and excess trauma to the axillary vein, sharp surgical dissection, weight reduction, and discriminate use of irradiation.

Inflammatory Lymphedema

This type is characterized by recurrent episodes of lymphangitis and cellulitis with chills, fever, and constitutional symptoms. When it occurs, the upper extremity becomes swollen, red, hot, and tender to the touch in a short time. Streptococci are usually responsible for the acute episodes, although staphylococci may be the cause. The regional lymph nodes are often swollen and tender, and the swelling may persist long after the signs of inflammation have subsided. If there is recrudescence, lymph channel thrombosis and fibrosis further obstruct the lymph vessels. The lymphedema may be primary or secondary to local injury, infection, or systemic disease.

Lymphangiosarcoma

Since Stewart and Treves'[24] report in 1948, 83 cases of lymphangiosarcoma, a rare malignant neoplasm seen most commonly in the lymphedematous arm after radical mastectomy, have been reported.[25] After an average cancer-free interval of eight years, purplish-red, subdermal, macular lesions arise on the arm or antecubital area; secondary satellite areas develop which may adjoin and continue to spread up the arm, and new lesions later appear on the adjacent part of the thorax. Neither the nature of the original neoplasm nor the recurrence of it seems to be a factor in this condition, for it has occurred after radical operation for benign breast diseases and has even been reported in chronic lymphedema of the lower extremities. Treatment consists of forequarter amputation with or without x-ray therapy or x-ray therapy alone; but death from pulmonary metastasis usually ensues shortly. For this reason, prophylaxis and treatment of lymphedema are imperative.

Treatment

Medical Treatment

It is as difficult to treat lymphedema as it is to prevent it, and many times the treatment is only palliative. It is important that, from the start, both physician and patient understand the chronicity of the swelling and realize that present measures aid only in controlling swelling but do not effect a cure. If possible, the patient should be hospitalized for a few days of bed rest so that the extremity can be elevated and as much edema fluid mobilized as possible. Diuretics taken orally may help but, except in very mild cases, will not control the swelling if used alone. Prophylactic administration of antibiotics should prevent recurrent cellulitis and lymphangitis. Babb and associates[26] noted excellent results in a small group of patients treated by prophylactic administration of penicillin. Local measures, such as careful hand care and avoidance of even minor trauma, are very important because even a trivial insult will cause decompensation when the lymphatic system is already in a precarious state.

The physiatric management, at the Mayo Clinic, of patients with postmastectomy lymphedema has been outlined by Stillwell[15] and is basically similar to the programs used at other institutions. The extremity is periodically elevated during the day and as much as possible during the evening. The physiatric program, given twice daily, consists of 60 to 90 minutes of treatment with a pneumatic pump followed by 10 minutes of manual massage; then instruction is given in the techniques of isometric exercises and bandaging. Gentle kneading and friction techniques of massage prove effective in increasing the lymph flow in the extremity. Opinions differ regarding the effectiveness of various pneumatic pumping devices, but Tinkham and Stillwell[27] concluded that, although a greater number of patients treated for three days or more obtained a 30% reduction of edema when a pneumatic pump was used, treatment not including such a device is worthwhile. Active muscular exercise is stressed because it increases the flow in lymph vessels and veins as a result of the muscular pumping action. Exercises are done as nearly isometrically as possible, with the arm bandaged.

The home-care program also consists of elevation of the extremity, elastic support, and isometric exercises; it should be adhered to in a rigidly systematized manner. The patient is told to avoid using the arm for household tasks for longer than 15 to 20 minutes at a time and to avoid local heat and hot environments which increase lymph and blood flow.

Continued

The most important single part of the treatment program is the use of adequate external elastic support. This provides tissue hydrostatic pressure and prevents transudation of fluids into tissue spaces. Early in the program, a double, three-inch, woven elastic bandage is used; later, a fitted sleeve of the Jobst type may be worn. The patient is told to wrap the arm before rising in the morning and to reapply the bandage several times during the day. Usually, six to 12 weeks are required for the arm to reach its minimal size and another two to three months for the connective tissue to shrink. The patient may then remove the bandage at various times at the end of the day and note the length of time before swelling returns. The time varies, but most patients can go for several hours daily without the elastic bandage.

Stillwell[28] pointed out that most patients have two chances in three of eliminating a third of their swelling in the first four or five days of treatment. After that, improvement is slow, and patients may do as well on the home-care program as they would in a physiotherapy section.

Schwartz[29] reported favorable results with the use of hyaluronidase by iontophoresis in the treatment of lymphedema in five patients. However, he also emphasized that elastic support is needed to prevent the swelling from recurring.

Surgical Treatment

Many surgical procedures, either physiologic or excisional, have been used for prevention or treatment of lymphedema.[30] The physiologic operations provide reestablishment of continuity of deep lymph vessels, prevent angulation of the axillary vein and interruption of the venous return, and obliterate the axillary dead space.[31] These include the Kondoleon operation, use of long silk or nylon sutures bridging the axilla, pedicle skin grafts around the area of lymphatic obstruction, and placement of absorbable gelatin rolls (Gelfoam) around the axillary vein and various muscles around the axilla to obliterate dead space and provide a lymphatic bridge. Although good results are still claimed with some of the surgical procedures, the great number and variety of procedures attests to their general ineffectiveness.

The excisional operations are done for severe and chronic cases of lymphedema, less commonly on the upper extremity. Indications for excisional treatment are increase in size of the extremity, significant impairment of function, repeated infection, unsightly appearance, emotional disturbances because of the deformity, and changes in the skin such as thickening, induration, and dermatitis.[32] Basically, the excisional operations consist of removing various amounts of skin and subcutaneous fascia down to the underlying muscle and closing the defect primarily or with a skin graft. These operations are not universally successful and leave much to be desired cosmetically; however, the incidence of recurrent lymphangitis and cellulitis is decreased postoperatively. The use of elastic support is again of paramount importance.

It is hoped that in the future a more physiologic method for the treatment of lymphedema will be found. Transplantation of lymphatic vessels and reconstruction of lymphatic channels may provide a new approach to the problem.

Clinical Path Conference

Childbirth and Sudden Death

A thirty-nine-year-old mother of eight children entered the St. Barnabas Hospital on the afternoon of September 26, 1964, in early labor. Except for the discomfort of severe varicose veins of the legs and the vulva, her pregnancy had been uneventful. She had gained 15 pounds. She had been observed by an obstetrician for the last seven months of her pregnancy. Her predicted date of delivery was September 21, 1964. Her hemoglobin on August 20 was 10.8 gm.% and on admission was 12.8 gm.%.

On admission the patient's blood pressure was 124/70. Her pulse and temperature were normal. The fetal head was high, and the cervix was not dilated. The fetal heart rate was 126. Between 1:00 and 2:00 p.m. the patient's membranes ruptured spontaneously. The amniotic fluid was stained with meconium. At 5:00 p.m. she became nauseated and vomited, but otherwise looked well. At 7:15 p.m. she complained of mild abdominal pain and then suddenly gasped and became cyanotic. No blood pressure or pulse could be obtained. She appeared to have swallowed her tongue. An anesthesiologist was called and administered oxygen. The patient's color return, but not the vital signs. Her cervix was fully dilated. She was taken to the delivery room where a viable infant was delivered by low forceps extraction at 7:45 p.m. The infant, a girl weighing nine pounds and seven ounces, was covered with deeply stained meconium. With the delivery of the head, 500 ml. of blood gushed forth. Following the expression of the placenta and massage of the uterus the patient lost about 200 ml. more of blood. While the delivery was taking place, she remained cyanotic without vital signs. She was given intravenous fluids, adrenalin, blood transfusions, Solu-cortef, and external cardiac massage; but she did not respond and was pronounced dead at 8:55 p.m.

Dr. Richard Reece

Dr. Mitchell, this was your patient. Have you anything to add to the history?

Dr. Mancel Mitchell

I was sitting at a desk across the hall from the labor room when this patient gave a gasp and became cyanotic. I came immediately and found her unconscious, with rigid, flexed upper extremities. A convulsion from toxemia was my first impression. She had a peculiar cyanosis in the upper half of her body. The anesthesiologist was in the hospital at the time, and the patient was given oxygen almost immediately. Her cervix was found to be fully dilated at this time with the presenting part on the perineum. An elective low-forceps extraction was done without delay. The baby was alive but died the next day. About 30 minutes elapsed between the mother's symptoms of dyspnea and shock and the delivery.

OB-GYN Resident: What was the blood pressure of the patient when she started vomiting?

Continued

Dr. Mitchell: No record of the blood pressure was recorded at that time.
Dr. Reece: Was there tenderness along the varicose veins?
Dr. Mitchell: No, none.

Dr. Richard Fliehr

What happened to the fetal heart tones when she had her first episode? Were they heard at the time or was there so much mass confusion that they were not then noted?

Dr. Mitchell

At approximately 5:10, when she was nauseated, the fetal heart was recorded at 162/minute. Shortly after this episode, the heart beats were recorded at 130/minute. There is no further record.

Dr. Fliehr

Was there any demonstrable blood loss after the bag of waters ruptured, or before the delivery?
Dr. Mitchell: No.
Intern: When the patient became cyanotic and the cervix was dilated, was the head engaged or was it floating?
Dr. Mitchell: When she arrived at the delivery room, the baby's head was on the perineum.
Dr. Fliehr: Was any mention made of the consistency of the uterus at any time?
Dr. Mitchell: No.

Differential Diagnosis

Dr. Fliehr: Now let's consider the diagnostic possibilities in order of probability. Does the audience have any suggestions?

Resident: Abruptio placenta with embolus.
Dr. Fliehr: What kind of embolism?
Intern: Amniotic fluid.
Dr. Fliehr: What other possibilities are there?

Dr. Reece: With the varicose veins, sudden gasping for breath and shock, pulmonary embolism from the legs must be considered.

Dr. Fliehr: A thromboembolic phenomenon is a possibility, but it is more likely to occur after delivery. What other kind of embolism is possible?

Resident: An air embolus.

Dr. Fliehr

Certainly any of these embolic phenomena — amniotic fluid, thromboembolism, or air — could have led to sudden death in a young, pregnant woman. But emboli are not the only causes of death. Let's consider other areas.
Resident: Uterine rupture was my first thought.

Dr. Fliehr

Uterine rupture is certainly a possibility, especially in this patient who complained of abdominal pains before death. However, it is unusual for a rupture to occur this late in labor, and it is unusual to deliver from below with a uterine rupture. With only a partial rupture, however, a baby can be delivered vaginally. The patient's bleeding brings another condition to mind.

Resident: Cervical tear.

Dr. Fliehr: Yes, but with a cervical tear, the bleeding is usually external. There is another possibility which bears no relation to the uterus. It happened to us once.

Dr. John Popowich: Cerebral aneurysm.

Dr. Fliehr

Yes, cerebral aneurysm, cerebral hemorrhage, or even an unsuspected brain tumor. But of all the possibilities mentioned, the most logical is an amniotic fluid embolism following a massive premature separation of the placenta or abruptio. Let's have the pathologist relate his observations. My diagnosis is abruptio placenta with amniotic fluid embolism.

Pathological Discussion

Dr. Reece

The body was very cyanotic around the upper extremities and face. There were large varicosities of the right leg and also the right vulva. Upon opening the abdomen, we found about 500 cc. of blood in the mesentery posterior to the descending colon. In this hemorrhagic defect we noticed some greenish particulate matter. The uterus itself weighed 1600 grams, and along the left lateral side, a 15-cm. tear stretched from the cervix to the round ligament. This was not at the point of attachment of the placenta. Otherwise, the abdomen disclosed no real lesions. In the inferior vena cava we found more particles of green material. The spleen was enlarged and weighed 350 grams.

The chest cavity disclosed a normal heart, with no arteriosclerosis in the coronaries. The heart was filled with unclotted blood, and after two hours, this blood still did not clot. The lungs were normal in weight at 350 and 300 grams, and showed focal edema and atelectasis in the posterior segments. There were no pulmonary emboli: no blood clots in the pulmonary arteries.

Microscopically, the lungs demonstrated numerous vessels and capillaries filled with keratin and squamous epithelial cells. In one vessel, a lanugo hair was identified. These observations, of course, confirm the presence of amniotic fluid emboli. There was no infarction of the lungs, but scattered patches of edema were observed. Other organs had a normal microscopic appearance.

Dr. Fliehr: Did anyone check the placenta to see if there was evidence of premature separation?

Dr. Mitchell: Yes, we checked it, but saw no evidence of separation.

Continued

Dr. Fliehr

The most common cause of rupture of the uterus is, of course, previous cesarean section, and, if it was a classical section, the rupture usually occurs before the onset of labor. This is not an absolute rule but a generalization. If it was a low cervical section, the rupture is more likely to occur during labor or at the time of delivery. I assume this girl had no previous cesarean sections. The other possibility is that during her gynecological career, she had a vigorous D and C with weakening of the uterine wall. This is often suspected but seldom proven. We had a patient with massive rupture of the uterus, who had a D and C three to four months before she became pregnant. That was the only plausible bit of history we could conceive of that could account for the rupture.

Certainly multiparity with an overdilated, overstretched uterus containing a large baby can lead to a weakened musculature of the uterine wall and possible rupture. I don't suppose the actual cause of the rupture is known in this patient. I am sure that many conjectures have been made, but I doubt if any final opinion has been arrived at. Is that right, Dr. Mitchell? Why should she rupture her uterus without any previous section or history of trauma?

Dr. Mitchell: We don't know.

General Comments

Dr. Fliehr

The phenomenon that actually caused death, the amniotic fluid embolism, usually occurs in elderly multigravida, with large babies and prolonged labor. Two of the facets are present here: she was an elderly multigravida and she did have a large baby; but she did not have a prolonged labor.

Emboli to the lung usually occur during or immediately after the delivery; it is unusual for them to occur before delivery. When the duration of labor is short, the predominant symptoms are pulmonary distress, shock, and death; and when prolonged, hemorrhage is a complicating factor with hypofibrinogenemia as an underlying cause. Atwood and Park, who examined the histological material from 220 parturient women,[1] found emboli from the trophoblast itself in over half of these women. The more sections they made of the lungs and the more special staining processes they used, the higher the incidence of the trophoblastic tissue found. They therefore concluded that almost all pregnancies have some trophoblastic emboli to the lungs.

In those patients in which emboli produce death, they attribute the excessive embolic material to "placental commotion," which can mean prolonged labor, uterine manipulation, or excessive contractions in eclampsia. Other factors such as placental infarction with a loosening of the trophoblastic tissue or its attachment to the villae could be contributory. In this case, the "placental commotion" was the rupture of the uterus, with probable placental infarction as well.

It is probably solid emboli rather than the systemic effects of amniotic fluid that cause the damage. Three men at the University of Sidney, Australia, injected amniotic fluid intravenously into two groups of sheep.[2] In one they filtered the amniotic fluid, and in the other they did not. In the filtered group, very little symptomatology was observed; whereas in the sheep given unfiltered amniotic fluid, the classical emboli phenomena were observed. This supported the concept of the Scots that solid emboli, not fluid, caused death. The incidence of amniotic fluid embolism is not high, but it is significant. At the Sloan Hospital for Women it is still the most common cause of maternal death during labor, delivery, and the immediate post-partum period.[3]

No effective treatment exists, especially in the massive case, as the patient is dead before heroic measures can be instituted. Oxygen by positive pressure is indicated. Some authorities advocate giving Papavarine hydrochloride for the reflex vasospasm. Atropine-like agents may be given for the cardiac depressive effects. Of prime concern, of course, is the treatment of shock with fluids, blood, and vasopressors, though with this injury to the lung already present, there is danger of promoting pulmonary edema, by the administration of excessive fluid.

If the amniotic fluid embolus occurs before the bag of waters is ruptured, amniotomy can be done to relieve intrauterine pressure, because increased uterine pressure may be the causative factor in pushing the emboli into the vascular system and thus into the lung. In almost all instances of amniotic fluid embolism the maternal fatality rate is extremely high. If the patients survive, it is usually pure chance.

While we are on this subject of embolism, let us consider air embolism. Criminal abortion accounts for the bulk of air embolism deaths; but if we exclude criminal abortion, air embolism can also occur at almost any time during delivery and the immediate post-partum period. There have been some recorded cases, for example, of it occurring in women who are put in a knee-chest position following delivery and during the post-partum period. Placental fragments can be dislodged in the knee-chest position, thus opening up the sinuses. Air can enter the uterus under negative pressure, enter the blood stream, and lead to fatal air embolism. There has been one reported case of a woman who merely flopped over in bed at night and from rolling over and lifting her leg, air entered into the vagina and the uterus with an air embolism. It can also occur by excessive manipulation of the uterus, especially following the expulsion of the placenta. This is one reason nurses should be instructed to be gentle with uterine massage.

In this particular case, without knowing the diagnosis, you might suspect premature separation of the placenta, because there is the same symptomatology as in the rupture of the uterus. There can be sudden abdominal pain with or without bleeding. Bleeding may be external or internal with dissection into the uterine tissue: a Couvalaire uterus. This gives abdominal pain. In the case of this unfortunate patient, a triple insult — amniotic embolus, rupture of the uterus, and hemorrhage — caused her death.

Dr. Mitchell

The latest report in the literature is from the University of Alabama Medical Center.[4] They list four additional cases and review symptoms, treatment, and pathogenesis. They also mention numerous therapeutic measures but emphasize the general ineffectiveness of treatment.

My original or provisional diagnosis as indicated on the chart was an

Continued

acute abruptio placenta with amniotic fluid emboli. I also included a possible embolus from the infected thrombus from one of her varicose veins and a ruptured intercerebral aneurysm. I was surprised to learn of the ruptured uterus; but when I review the clinical story, I realize I should have thought of it first. The patient was a multipara with a large baby — both predisposing factors in rupture — but the lack of tumultuous labor and the lack of history of previous sections were against rupture. In the cases which were reported by the Minnesota Mortality Committee, half of them received oxytocin. This lady did not receive any oxytocin at any time, until after the placenta was delivered.

As we review this story now, rupture of the uterus is the most logical explanation and is something we have to consider with amniotic embolus. The incidence of death from amniotic fluid embolus varies from one in every 8,000 to one in 37,500 deliveries.[5,6] In Minnesota in a 20-year period, ten cases have been documented.

Dr. Reece

I would like to add something about the incidence. In Ontario from 1958 to 1960, 469,000 deliveries were studied.[7] In this group of patients 280 died: five of amniotic fluid embolus — an incidence of one in every 93,800 deliveries. Pulmonary embolism accounted for 14 out of 280 and air embolism for 12 out of 280: both more frequent than amniotic fluid embolism. As for the causes of maternal death among the 280 women, hemorrhage accounted for 33%, toxemia 12%, infection 23%, vascular accidents (including all types of emboli) 16%, anesthesia 7%, and miscellaneous 9%.

There are more than 100 reported cases of amniotic fluid embolism in the literature — 14 of which were nonfatal. The diagnosis of amniotic fluid embolism is one of exclusion. The only way to conclusively demonstrate it is to show amniotic fluid elements in the right heart; but it should be suspected in a patient who goes into sudden shock and shows the clinical or x-ray picture of pulmonary edema. Rupture of the uterus is a well known factor in producing amniotic fluid emboli.[8,9] The emboli, rich in thromboplastin, lead to widespread defibrination of the maternal blood, and consequent hemorrhage. In the Ontario study, 79 of the 280 maternal deaths were attributed to hemorrhage. Of the deaths from hemorrhage, 31 were the result of uterine rupture.

Anatomical Diagnosis

Spontaneous rupture of uterus with hemorrhage
Amniotic fluid emboli
Possible hypofibrinogenemia

Grand Rounds

The Treatment of Multiple Sclerosis with ACTH*

Multiple sclerosis, by definition, is a demyelinating disease of the central nervous system, characterized by diffuse neurological deficits and an unpredictable clinical course marked by remissions and exacerbations. The etiology is unknown, and there is no known cure. Many different forms of therapy, ranging from Vitamin B_{12} injections to the intrathecal administration of tuberculin, have been tried and, for the most part, abandoned as ineffective.[1] The use of adrenocorticotrophic hormone (corticotrophin, ACTH) has, however, achieved relatively wide acceptance as the best method available at the present time for the treatment of multiple sclerosis. The status of this form of therapy is the main topic of this presentation.

Short Term Therapy Without Control Studies

The use of ACTH in the treatment of multiple sclerosis was first undertaken by Jonsson et al.[2] in 1949. Using initial doses of 25 mg., followed by 5 mg. every three hours to a total dosage of 300 mg. of ACTH, they reported improvement in two new cases but none in chronic cases.

In 1952, Fog[3] reported 20 cases and claimed improvement in 15 of them. Little attempt was made by him to categorize his patients according to age, sex, duration of disease, etc., and he did not employ any controls.

Merritt and Glaser[4] in 1952 reported a series of 33 patients treated with ACTH, none of whom had had remissions for at least three years prior to treatment. They reported significant improvement in 12 (36%) of their patients and either no change or mild alterations in the remainder. The effects were all transient, with a tendency towards relapse after discontinuation of the drug. In addition, these authors determined cerebrospinal

fluid protein on all their patients before and after treatment and found no significant changes (Table 1).

TABLE 1
Effects of Corticotropin and Cortisone on Specific Symptom Complexes in Thirty-Three Cases of Multiple Sclerosis

Symptom Complex	Total No. Patients with Syndrome	Improvement Rating				
		1—	0	1+	2+	3+

Ocular movement	23	0	19	3	1	0

1— = slightly worse, 0 = no change, 1+ = slight improvement, 2+ = moderate improvement, and 3+ = pronounced improvement.
From Glaser, G. H., and Merritt, H. H.: Effects of Corticotropin (ACTH) and Cortisone on Disorders of the Nervous System. JAMA 148:898, 1952.

A similar study was reported by Rowland and Randt[5] in 1953, employing nine patients. These investigators found no improvement in any of their cases. In none of the aforementioned studies were control groups used. Merritt and Glaser used their treated patients as their own controls, but this was as close as anyone came to controlling his experiments. A second difficulty is encountered in attempting to interpret the extent of the patients' clinical response for purposes of comparing the results of one series with another, since there appears to be little uniformity between the various investigators' criteria.

Controlled Studies

Alexander, Berkeley and Alexander[6] in 1958 observed 554 patients for a total of 1,412 patient years, studying the natural course of the disease and its response to various forms of treatment. They used a scoring system devised earlier by Alexander[7] which consisted of assigning various numbers of points to different neurological signs and symptoms with a scale ranging from 0 (no neurological deficit) to 500 (completely bedridden and helpless). The progression and regression of the score was representative of the course of the disease when compared to the patient's subjective report, his ability to perform tasks, the social worker's report and the impression of the clinical examination. It also appeared reliable, with a correlation coefficient of 0.95 between scores obtained by six different examiners. Using this system they obtained data quantitating the course of the disease with correlations between numbers of exacerbations, their duration, severity, acuteness of onset and the level of disability before and after the attacks. They then selected 22 patients for treatment with ACTH and compared them with 22 control patients matched by age, sex, duration of illness and disability score at the time of initiating treatment and over the preceding three to 12 months. The average interval of treatment was three months, and the result obtained was an average reduction in disability score of 80 in the treatment group. This change was felt by the authors to be statistically significant (Figure 1).

FIGURE I
*Average Change in Disability Score in Patients Treated with ACTH

ACTH Regime

By 1963, Alexander et al.[8] had treated 110 cases of multiple sclerosis and again reported their experience. Using control and treatment groups as before, they tested patients on four different regimens:

1. High dosage ACTH for three months.
2. High dosage ACTH plus maintenance treatment.
3. Low dosage ACTH for three months.
4. Low dosage ACTH for one to four years (average 24 months).

They then grouped these patients into grading categories based upon the percentage reduction in the average pretreatment score. Grade A included all patients with a reduction in disability score of 40% or more; Grade B, all patients with a 25% to 39% reduction in score; and Grade C, all patients with a 10% to 24% reduction in disability score. Their results (Table 2) in general show significant response in Groups 1 and 2, with marked diminution in response in Groups 3 and 4. The questions of dosage and maintenance treatment will be considered later in this paper.

Prednisolone & Acetylsalicylic Acid Regime

In 1961 Miller, Newell and Ridley[9] conducted a study in which they attempted to evaluate the effects of prednisolone and acetylsalicylic acid on multiple sclerosis. Their 86 patients were randomly allocated to control and treatment groups, which were then compared and found equal for the following characteristics: sex, age, duration of disease and recent course (slowly progressive, fluctuant, rapidly progressive). The patients were evaluated on the basis of the Alexander score, the number of acute exacerbations, the number of new symptoms and signs appearing during the trial, and the patients' own subjective assessment 18 months after the institution of treatment. All patients were evaluated before and during

Continued

treatment by the same examiner, who was unaware of the treatment group to which any given patient belonged. Prednisolone was found to have no effect on the course of the disease, and the effect of acetylsalicylic acid was inconclusive.

However, in a study reported later the same year, the same authors[10] found more significant results for ACTH. They chose, out of a total of 120 referred patients, 40 who had unequivocal multiple sclerosis with new symptoms or signs of less than 14 days' duration, with no evidence of spontaneous improvement. These patients were divided into two groups (treatment and control) which were comparable as to age, presence of acute exacerbation and significant acute deterioration. The treatment group contained relatively more patients who were experiencing the initial episode of their disease (six compared to two for the control group). Patients in the treatment group received a three-week course of therapy consisting of 60 units ACTH gel intramuscularly twice daily for the first week, 40 units twice daily for the second week, and 60, 40 and 20 units daily on the second, fourth and sixth days respectively of the third week. The control patients received intramuscular injections of normal saline following the same schedule. In evaluating the results it was found that changes due to exacerbation represented too small a fraction of the total disability to use the Alexander scores, so the evaluation was necessarily subjective, using three categories. The authors pointed out, however, that the same examiner had evaluated all the patients and that he was unaware of the group to which each patient belonged. The three categories used were *Category A*, including all patients showing significant improvement within a few days, with their exacerbation entirely or almost entirely cleared by three weeks; *Category C*, including all patients showing no significant

TABLE 2

Effect of ACTH Therapy in Patients with Multiple Sclerosis Compared with Untreated Controls*

Group	N	Grade A (Reduction in Disability Score by 40% or More) % of N	Grade B (Reduction in Disability Score by 25% to 39%) % of N	Grade C (Reduction in Disability Score by 10% to 24%) % of N	No Improvement % of N

improvement after three weeks; and *Category B,* including those patients who did not fit clearly into either A or C. It was found that of the 22 treated patients, 11 were in Category A, eight in Category B and three in Category C. Results for the control group (18 patients) showed four in Category A, seven in Category B and seven in Category C. These results were felt to be statistically significant, even though the method necessary for evaluating the patients' responses was somewhat suspect.

Dosage

The dosages of ACTH employed by various investigators have varied considerably. Jonsson et al.[2] used initial doses of 25 mg. of Cortrophin (Organon) and subsequent doses of 5 mg. up to a total dose of 300 mg. Fog[3] used between 40 and 50 mg. of Acton preparations (Frederiksberg kemiske fabrikker) but did not have any well planned schedule of dosage set up. Glaser and Merritt[4] employed ACTH (Armour) in doses of 80-100 mg. per day for periods of five days to two weeks. The later studies used dosages expressed in terms of International Units of ACTH; one I.U. equals the biological activity of 1 mg. of international standard as determined by the adrenal ascorbic acid depletion method,[11] giving a more uniform dosage than before. The dosages used by Miller et al.[10] have already been mentioned. Alexander et al.[8] used two different dosage schedules, high and low, in addition to keeping some patients on maintenance doses for periods of up to six years. Patients on high dosage received 40 units of ACTH intravenously per day (or equivalent dosage of 60 units ACTH gel I.M. every 12 hours) for the first 10 days. They were then given 60 units of ACTH gel I.M. twice daily for 10 days, followed by gradual reduction of the daily dose by 20 units every three to five days until a maintenance dosage of 40 units daily was reached on approximately the 32nd day of treatment. This dose was then reduced variably until most patients were receiving not less than 20 units of gel three times a week. The low dosage regimen was identical with the maintenance phase of the high dosage regimen, i.e., 40 units of gel per day. The results (Table 2) were best for the high dosage regimen, especially when maintenance therapy was added.

Maintenance Therapy

Long-term maintenance therapy has apparently received serious attention in only a few centers. Alexander[10] has used it for as long as six years without apparent ill effect. Paulley[12,13] has used up to 40 units per day for several years without apparent ill effect and with supposedly successful prevention of exacerbations. However, his communications (in the form of letters to the British Medical Journal) do not seem detailed enough to draw any more than very tentative conclusions. Miller[1] maintains some of his patients on variable dosages for periods of three to six months but has a cautious attitude towards more long-term "prophylactic" treatment. At present there is little agreement on this subject.

Side Effects

In most of the series reported there was very little mention made of the side effects of ACTH, although they are generally felt to be less common

Continued

and less severe than those of corticosteroids.[1] The only authors found who dealt with them in any detail were Alexander and Cass.[8] They studied 12 of their patients receiving high doses of ACTH and divided the side effects into three groups, summarized below:

Group A (Onset on treatment days 5-24, average 12):

1. Superficial emotional excitement — 5 patients (1 equivocal)
2. Subjective G.I. symptoms — 3 patients
3. Tachycardia — 1 patient

Group B (Onset on treatment days 9-40, average 25):

1. Edema — 6 patients
2. Acne — 4 patients
3. G.I. bleeding (Guaiac positive) — 2 patients
4. Leukocytosis — 3 patients (16,200 to 20,400)
5. Infection — 4 patients
6. Mucous colitis — 1 patient
7. Pathologic fractures — 2 patients
8. ECG changes — 2 patients (1 equivocal)
9. Albuminuria — 1 patient

Group C (Onset on treatment days 21-60, average 34):

1. Hypotension — 3 patients (108/80 to 50/?)
2. Vertigo, syncope, dimness of vision — 4 patients
3. Hypoglycemia — 1 patient (FBS 75 mg%)
4. Hyperglycemia — 4 patients (120 mg% to 350 mg%)
5. Electrolyte changes — 4 patients:
    a. K increased
    b. CO_2 increased, Cl, Na decreased
    c. CO_2 increased, Cl, Ca decreased
    d. Na, Cl, Ca decreased
6. Mental changes — 8 patients (major psychoses in 4 patients)
7. Melanoderma — 1 patient
8. Death — 1 patient

Group A side effects were considered to be due to stimulatory effects of ACTH, Group B side effects to tissue changes, and Group C side effects to adrenal exhaustion. These side effects were correlated with the excretion of urinary 17-ketosteroids and 17-hydroxycorticoids which formed a curve showing three peaks and three troughs during the first sixty days of treatment on the average. The average onset of Group A side effects occurred at the height of the first peak (average day 12), Group B near the depth of the second trough (average day 26), and Group C near the onset of the third trough (average day 35).

Conclusions

Most of the available reports on the treatment of multiple sclerosis with ACTH are, at present, scant and mostly equivocal. For the most part they are uncontrolled, and there has been little attempt to standardize criteria for evaluation of clinical response, although this is very difficult. The most well controlled studies, however, support the value of ACTH treatment in acute exacerbations of the disease. There is even less evidence available on long-term maintenance therapy than on the use of ACTH for acute exacerbations; so the question of maintenance therapy is entirely an open one. The incidence of side effects is not discussed much, but it appears to be very low. However, the possibility of adrenal insufficiency during ACTH therapy apparently exists and should be watched for.

Case Report

A 53-year-old white female was admitted to Mount Sinai Hospital on March 3, 1965, with chief complaints of difficulty swallowing, stiff neck, lump in the left side of the neck and ease of fatigability. The history of her present illness dates back approximately three years prior to admission, at which time she noted onset of dysphonia and hearing loss in the left ear. She was seen at the University of Minnesota at that time, where paralysis of the left vocal cord and nerve deafness of the left ear were noted. Since then she had been noticing dysphagia for foods and easy fatigability.

Pertinent past history includes hypertension diagnosed eight years ago, and hypothyroidism diagnosed seven years ago. At admission, she was taking antihypertensive medications and grains three of thyroid daily. She was suspected at one time of having myasthenia gravis, but extensive workup failed to establish that diagnosis. General physical examination was negative except for a localized spasm of the left sternocleidomastoid muscle and paralysis of the left vocal cord. Neurological examination revealed a diminished right corneal reflex, a marked left N.VIII deficit, and hyperreflexia of the left triceps reflex. There was a questionable Hoffmann sign on the right and some dysmetria on the left.

Laboratory data including urinalysis, CBC, serum Na, K, proteins (total and A/G ratio), Ca, P and cholesterol were within normal limits. CSF examination revealed a glucose of 65 mg%, chlorides 602 mg%, protein 29 mg%, and negative VDRL, Wasserman and colloidal gold determinations. A muscle biopsy to exclude polyarteritis nodosa was negative. A consulting neurologist favored the diagnosis of multiple sclerosis and suggested a trial of ACTH therapy. Accordingly, the patient was placed on 25 units of ACTH intravenously per day for 14 days. There was no objective or subjective response to therapy and the patient was discharged on March 25, 1965.

*Mechanism and Management of Intravascular Thrombosis**

JOHN A. SPITTELL, JR., M.D.**
JOHN H. THOMPSON, JR., Ph.D.†
CHARLES A. OWEN, JR., M.D.†
Rochester, Minnesota

INTRAVASCULAR THROMBOSIS with its complications continues to be a problem for physicians in all types of practice. To date the understanding of the mechanism of thrombosis remains incomplete; however, certain factors appear to play some role in its causation, and an understanding of these is important in developing a therapeutic approach to the problem.

Consideration of the number of clinical situations in which thrombosis occurs suggests that multiple mechanisms of thrombosis exist. More than 100 years ago Virchow[1] proposed that three factors were important in intravascular thrombosis: (1) changes in the blood vessel, (2) stasis or slowing of the blood flow, and (3) altered blood coagulability. Despite the efforts of many investigators since Virchow, the relative importance and interplay of these factors in thromboembolism are still not clearly understood.

Blood Vessel Damage

The causative role of vessel damage in the formation of a thrombus seems plausible in inflammatory vascular diseases, degenerative arterial disease, and surgery or trauma, particularly of the blood vessels themselves. The mechanism of thrombosis secondary to vessel damage may be related to changes in electrical potential. Normally the endothelial surface of a blood vessel is electrically negative with respect to its wall, but the negative charge is lost with injury.[2] Experimentally it has been shown that thrombosis can be readily induced when a positive electrical potential is applied to a vessel wall; but if the potential is negative, it is almost impossible to induce thrombosis in the vessel.[3] The normal negative charge of the endothelium would tend to repel the platelets, which are also negatively charged.

Platelets

The probability that a mechanism involving platelets is operative in certain thrombotic disorders has considerable experimental and clinical support. The sequence of events which follows trauma to the endothelium of a vein has been studied by Wright.[4] Initially there is a deposition of platelets at the site of injury, followed by fusion of the platelets to form a plaque. The plaque enlarges and finally obstructs the blood flow, and ultimately the stagnant column of blood becomes clotted. Further evidence that platelets may be involved in thrombotic mechanisms is their content of phospholipids, which will accelerate clotting in vitro.[5] In addition, platelets have the property of adhesiveness, which is increased in the postoperative and post-traumatic states,[6] in both of which there is an increased incidence of thromboembolism. An increase in the number of platelets may be conducive to thrombosis, for conditions in which thrombocytosis occurs, such as polycythemia vera and the postoperative period after splenectomy, are not infrequently complicated by thrombosis.

Stasis

The importance of stasis in the formation of intravascular thrombi is suggested by the frequency of thrombosis in patients who are immobilized in bed as a result of surgery, parturition, or trauma, in patients with congestive heart failure, and in persons with varicose veins. Associated with slowing of blood flow there may be settling of its suspended particles, or "sludging," a phenomenon that has been well demonstrated experimentally by Knisely and his associates.[7] However, the exact role of "sludging" as a mechanism of thrombosis remains conjectural.

Hypercoagulable Blood

Numerous studies of the coagulation mechanism lend support to the concept of hypercoagulable states. Decreased responsiveness to heparin[8] and changes in standard tests of coagulation[9-11] have been reported in various thrombotic states, but most of the established clotting tests (coagulation time, prothrombin time, and prothrombin consumption) are not suited, by design, for the detection of hypercoagulability.

Expansion of knowledge of blood coagulation in recent years has been concerned principally with the nature of plasma thromboplastin and its formation. The suggestion of a relationship between increased coagulability and increased thromboplastic activity by several investigators[12,13] seems logical, since, in vitro at least, the formation of thromboplastin is the longest phase of clotting, requiring more time than all the subsequent steps of coagulation combined (Table). By means of the thromboplastin generation test (TGT), as designed by Biggs and Douglas,[14] it is possible to study the earlier phases of coagulation. With the thromboplastin generation test or a modification of it,[15] evidence for hypercoagulability has been found in both idiopathic[16] and secondary thrombophlebitis,[17] in acute ar-

TABLE I

Step 4.	Conversion of fibrinogen	Fibrinogen $\xrightarrow{\text{Thrombin}}$ Fibrin

terial thrombosis,[18] and in coronary artery disease.[19]

Studies of known coagulation factors have shown increases in the quantities of these factors in clinical conditions that predispose to thrombosis, but as yet there is no more than circumstantial evidence that increased amounts of a clotting factor can cause intravascular thrombosis. Following trauma or surgery the concentration of fibrinogen increases.[20] During pregnancy there is an increase in levels of stable factor (VII) or of Stuart factor[21] (X) or of both. Antihemophilic globulin (VIII) has been found to be increased in the postoperative state[17] and in patients with large or metastatic cancer,[17] chronic ulcerative colitis,[22] and coronary artery disease.[23] Excessive amounts of a previously unrecognized clotting activity, tentatively named thromboplastin generation accelerator (TGA), has been reported in some cases of idiopathic recurrent thrombophlebitis and in patients with acute arterial occlusion complicating arteriosclerosis obliterans.[24]

Finally, there is experimental evidence supporting the concept of hypercoagulability. It has been shown that serum contains an activity which, when the serum is infused systemically, will consistently produce thrombosis in isolated venous segments of animals.[25] Furthermore, this activity of serum has been shown to be related in some way to specific coagulation factors [Christmas factor (IX) and Hageman factor (XII)].

Although there is increasing evidence that hypercoagulable states may exist, due perhaps to multiple mechanisms, all authorities do not agree on this. Perhaps the best evidence for hypercoagulability is the efficacy of anticoagulant drugs in the prevention of thrombosis as well as in its treatment.

Management of Thrombosis

The principles of the management of intravascular thrombosis are probably best reviewed by a consideration of deep venous thrombosis. Before the definitive treatment of venous thromboembolism is discussed, it is important to stress the need for preventive measures. Clinical experience indicates that during the postoperative period after pelvic surgery, splenectomy, or abdominal operations for malignant disease, the incidence of venous thromboembolism is increased. Furthermore, patients with a history of venous thrombosis, or those with leg trauma, cardiac disease, malignant lesions, or obesity are more prone than other patients to experience venous thrombosis when immobilized in bed. In the aforementioned situations, in which an increased risk of venous thrombosis is present, measures to minimize venous stasis and prophylactic anticoagulant therapy are indicated (provided no contraindications exist).[26]

General Measures

The therapeutic program for deep venous thrombosis should include measures to relieve venous congestion and restore venous flow as well as measures to prevent further thrombosis and pulmonary embolism. There is agreement concerning such general measures as rest in bed, elevation of the involved extremity, and relief of pain; but there is no unanimity about definitive therapy, some advocating anticoagulant therapy, others thrombolytic therapy, and still others vein ligation.

Vein ligation, while appealing from the standpoint of preventing pulmonary embolism, offers no protection against further thrombosis in other sites. The dissolution of thrombi by lytic enzymes is a promising therapeutic approach to venous thrombosis; but at present, problems of laboratory control, dosage, and methods of inducing lysis are not sufficiently standardized to justify its routine use.[27]

Thrombectomy without Ligation

Thrombectomy without venous ligation followed by anticoagulant therapy has been advocated by several investigators for the treatment of acute iliofemoral thrombophlebitis.[28-30] After removal of the thrombus, relief of venous congestion has been observed. Postoperative anticoagulant therapy is administered to prevent re-thrombosis. Advocates of this procedure feel that the incidence of chronic venous insufficiency will be re-

Continued

duced, but whether results are superior to those obtained with conservative treatment with anticoagulants will require additional study.

Anticoagulant Therapy

Assuming the probable role of hypercoagulability in the pathogenesis of thrombosis, anticoagulant therapy has, in our opinion, distinct advantages over the other methods of treatment. Not only should an adequate anticoagulant effect prevent further thrombosis, but there is evidence that anticoagulant therapy also hastens the recanalization of the thrombus. The use of anticoagulant drugs carries the hazard of bleeding; but sufficient experience with these drugs has been accumulated to minimize this complication, provided dosage is regulated by adequate laboratory tests.

Heparin is a mucopolysaccharide that exerts its anticoagulant effect immediately on contact with blood. The anticoagulant effect of heparin results mainly from its antithrombin action (Table) ; in addition, heparin appears to inhibit the earlier stages of clotting and to reduce platelet adhesiveness; and, since it carries a strong negative charge, heparin may impede thrombosis by altering the electrical potential of blood. Since heparin must be administered parenterally, and since its effect is dissipated relatively rapidly, it is best suited to short-term use when an immediate anticoagulant effect is desired.

The other group of anticoagulant drugs, the coumarin and indandione derivatives, are usually administered orally, and they differ from heparin in several other ways. These drugs exert their anticoagulant effect by depressing the levels of stable factor (VII), Stuart factor (X), Christmas factor (IX), and prothrombin (II) (Table). Following the administration of an adequate dose of one of the orally administered anticoagulant drugs, there is a period of 24 to 48 hours before the full effect is manifest; a similar lag occurs when administration of these drugs is discontinued. Of paramount importance in the use of the oral anticoagulant drugs is the availability of adequate laboratory facilities for performance of the prothrombin time, the test most widely used to control the dosage of these drugs.

Not uncommonly in the treatment of acute venous thrombosis we employ both heparin (for its immediate effect) and an orally administered anticoagulant at the onset. When adequate anticoagulant effect from the oral anticoagulant has been established, use of the heparin is discontinued and anticoagulation is maintained with the oral agent. The various orally administered anticoagulant drugs, their dosage, and the contraindications to their use have been discussed elsewhere in detail.[31,32,33]

Short-term anticoagulant therapy has been effective not only in the treatment of venous thromboembolism but also in the prevention of subsequent thromboembolic episodes in patients who have had previous venous thrombosis. Anticoagulant therapy is basic in the management of thrombotic disease, and its efficacy lends support to the concept that hypercoagulability of the blood is an important factor in the occurrence of intravascular thrombosis.

Summary

A rational approach to the management of intravascular thrombosis should be developed on the basis of its etiology. Unfortunately, the mechanism of thrombosis is not completely understood; however, changes in the blood vessel, flow, and coagulability all appear to have some role. In recent years, there has been increasing evidence for the probable importance of increased blood coagulability in thrombotic disease. For this reason, the anticoagulant drugs seem basic in both definitive and prophylactic therapy of thrombosis.

Abstracts, Briefs and Commentaries

PATHOGENIC MICRO-ORGANISMS

Although everyone is exposed to pathogenic micro-organisms many times every day, the incidence of infectious diseases is relatively low. It is accepted that the host-parasite relationship determines the eventual occurrence and course of most infectious illnesses and that many environmental and genetic factors are implicated in their epidemiology. Psychological factors have also been suggested as etiologic determinants, but, because it is difficult to control or measure such factors, human data are relatively sparse. In this investigation, the authors demonstrated that mice under psychological stress (periodic paired light and shock) had an increased susceptibility to Coxsackie B virus, as measured by variations in body weight. This particular series of experiments exquisitely illustrates the principle of multifactorial etiology even in such seemingly straightforward problems as infectious diseases. The concept of multifactorial etiology is probably important in many areas of medicine, and psychological factors probably participate in many illnesses that have an ostensibly organic etiology.

GASTRIC FREEZING FOR DUODENAL ULCER

Since 1962 there have been conflicting opinions in regard to the benefit of gastric freezing for duodenal ulcer. For a time it was thought that the extent of the freezing might be a factor in providing beneficial results. Scott and co-workers in Nashville, Tennessee, studied a series of 60 patients and classified their results into three groups, depending on the extent of the temperature of the returning coolant.

In most instances all patients obtained initial symptomatic relief despite the fact that there was no significant suppression of the gastric acidity.

Continued

Approximately one third of the patients required subsequent operation for recurrent or persistent symptoms. It was considered that gastric freezing in its present form would never replace definitive surgical intervention in the treatment of chronic duodenal ulcer.

It would seem that gastric freezing for duodenal ulcer should be carried out only in institutions where clinical research can be fully evaluated. It has no place in the armamentarium of the physician who is in private practice.

GASTRECTOMY IN INFANCY AND CHILDHOOD

This paper was prompted by the little known hazards and indications for gastrectomy in infancy and childhood. Most of the apprehension concerning gastrectomy in childhood is based on gastrectomy in adults. The only experimental study of the problem was done by Thompson, Bonta, and Chatworthy in 1956, who found that healthy puppies subjected to 50% gastrectomy, vagotomy, and gastroduodenostomy at three weeks of age gained weight the same as control litter mates.

Data were furnished by a questionnaire sent to the American Academy of Pediatrics and the British Association of Pediatric Surgeons, an international group. Information concerning 113 gastric resections during the first 12 years of life was collected. There were 98 resections with ten per cent operative deaths. There were three late deaths due to cancer. Ninety-eight resections were done in the first two years of life. All ten deaths were in patients six years of age or younger, five of whom were four months of age or younger. Ninety-eight resections were subtotal distal or total and fifteen were esophagogastric.

Indications for resection were peptic ulcer (42 cases), gastric scarring or perforation resulting from ingestion of toxic material, lye or caustics (13 cases), duplication of the stomach (11 cases), and benign and malignant neoplasms (7 cases each). All but one of 15 esophagogastric resections were carried out for esophageal varices or esophagitis complicating hiatal hernia. There were two operative deaths. The lesions leading to operation in all fatal cases were bleeding, perforation, or both. The most significant finding of this study was the consistently normal growth and development following distal subtotal gastric resection or even total gastrectomy. Resection involving the cardioesophageal junction on the other hand was associated with a high degree of retardation of growth and development.

The Billroth type of reconstruction was most often used and comprised 83% of operations performed for peptic ulcer. Peptic esophagitis and "tampering" with the cardioesophageal junction were poorly tolerated by the growing child.

There was insufficient experience in this survey to assess the role of added vagotomy. The known high incidence of marginal ulceration in infants with peptic ulcer managed by gastroenterostomy alone suggests that vagotomy and antrectomy may be indicated.

Discussion

This international survey may be the first one of its kind. It is interesting to note that gastric surgery can be tolerated in infancy and childhood.

There are several pages of charts and tables giving minute details of age, operation, etc. I am much impressed by this excellent review.

BLEPHARITIS

The great variety of medication suggested for blepharitis reflects our essential ignorance of specific etiology. While the authors declare that they do not wish to discourage the search for specific agents, they feel that their own experience as well as that of others indicates that such specificity seldom will be found. Two general types encompass the vast majority of lid inflammation seen in general practice: seborrheic and ulcerative. In the seborrheic type the lid is reddened, with dry or greasy scales at the base of the lashes; in the ulcerative, the lid border is reddened, more in some spots than others, often with small pustules and loss of lashes. Because specificity has not been established, the authors feel that management should stress adequate lid hygiene, and they report a study of a series of 30 cases treated solely with a preparation combining antiseptic and keratolytic agents with sodium versenate (Blef-Dome, Dome Chemical Co.) The rationale on which its use is based is the penetration of cells by the chelating agent to permit lower concentrations of the antiseptic and keratolytic agents. Results showed that the majority of patients with uncomplicated blepharitis of the seborrheic type were sufficiently improved so that the frequency of medication could be reduced from twice daily to once every week or two, provided hygienic care was maintained. The ulcerative type responded more slowly; nevertheless, signs and symptoms diminished progressively with diligent care and therapy. In patients with blepharitis of the ulcerative type, treatment must be virtually unremitting, with daily attention to the eyelids.

The patients came from private practice and the general ophthalmology clinic of a medical center. The authors tabulate the cultures of organisms occurring singly and in combination taken from scrapings of the lids of these patients before and after therapy. After the bacterial studies were completed the patients were told to place the ointment on a cotton-wound toothpick with which they were to massage the lid margins and the roots of the eyelashes morning and evening. The treatment was to continue until all the scales were removed. Therapy was carried out twice daily until the lid margins were clean. After that, the massage was carried out once a day; then once every other day; then as required. No antibiotics, steroids, or other medications were used in any patient.

After therapy the number of patients with normal lid flora increased from 8 to 24. The authors tabulate the complete list of before-and-after cultures from eyelid scrapings, not repeated here. Tolerance to medication was excellent. Over a two-and-a-half year period only 2 cases of lid sensitivity have been seen out of a total of over 250 patients treated. The sensitivities disappeared when the drug was stopped.

CONTROL OF INFECTIONS IN HOSPITALS*

The occurrence of infections in hospitals is of deep concern to patient, physician and hospital administrator. The sporadic occurrences of infections in nurseries and nursing mothers and the fairly frequent occurrence of infections in supposedly clean surgical cases confirm the fact that the problem of hospital infections is still with us and requires constant vigilance for their limitation and control. Therefore, the Joint Commission on Accreditation of Hospitals in August, 1958, recommended that every hospital have an "Infection Committee" charged with the responsibility of investigation, control, and prevention of infections within hospitals. An attempt to evaluate the degree of compliance and success of such "set-ups" in Minnesota hospitals has been made through the distribution of a questionnaire to 45 hospitals in Minnesota — each containing 100 or more beds. The replies indicate that, in general, a serious attempt to comply with the recommendations made by the Commission on Accreditation of Hospitals has been made by the 36 hospitals answering such questionnaire. Several weaknesses and deficiencies in these "set-ups" and recommendations for their correction are made by the writer. Such recommendations include (1) the granting of regulatory powers to the "Infection Committee," (2) the elimination of added charges for isolation to those patients contracting infections in hospitals after their admission as a "clean case," and (3) setting up of larger "area" infection control committees made up of representatives of each individual hospital's infection committee, local and state health departments, and the medical society for the purpose of determining basic measures of detecting and reporting on infectibility and the control of infections in that area. Such measures, the writer feels, are in accord with the recommendations made by the "Accreditation of Hospitals" committee and could well be the added procedures needed to more completely minimize infections occurring in our hospitals.

VENOM FATALITIES

There were 460 fatalities from venomous animals in the United States from 1950 through 1959, an average of 46 deaths per year and an average annual death rate 0.28 per 1,000,000 population. *Hymenoptera* insects (bees, wasps, hornets, yellow-jackets, ants) killed 229 (50%) persons, poisonous snakes killed 138 (30%), and poisonous spiders killed 65 (14%). Scorpions, *Coelenterata,* stingrays, and unidentified venomous animals also caused deaths. Two spider bite deaths were caused by brown spiders *(Loxosceles recusus);* whereas *Latrodectus* spiders caused the other spider bite deaths. Usually several hours elapsed before people died from bites by venomous snakes and spiders. Most deaths from *Hymenoptera* insect stings took place within one hour and resulted from insect allergy. Most fatalities from venomous animals happen from April through October.

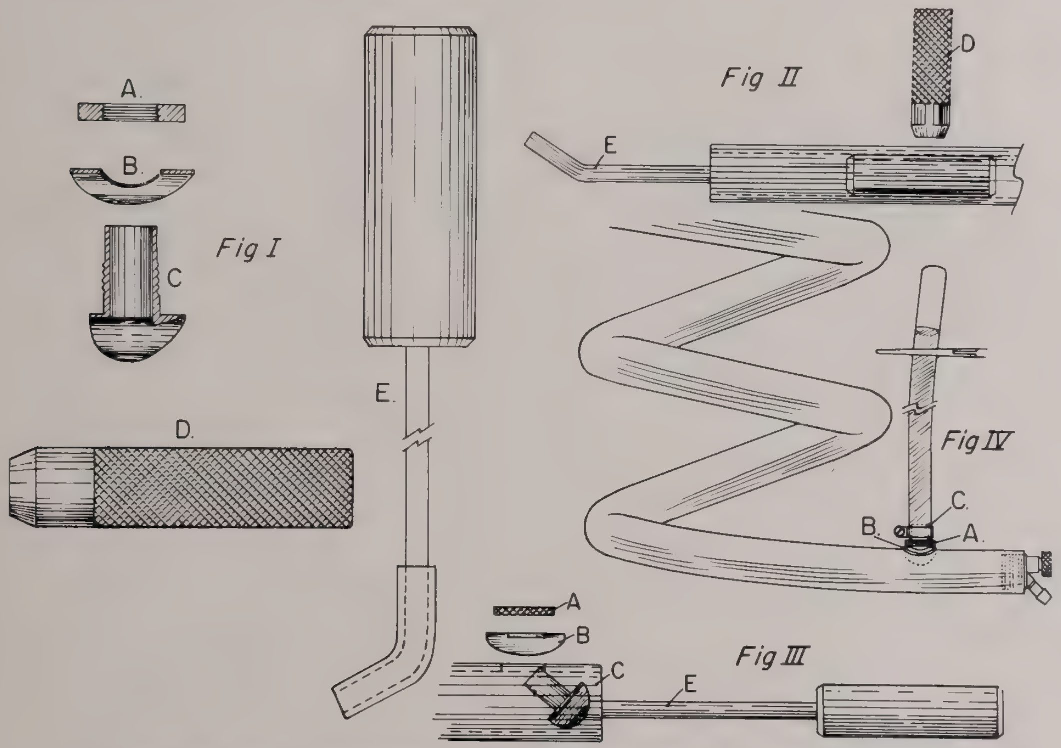
This Being of mine . . . consists of a little flesh, a little breath, and the ruling Reason. — Marcus Aurelius

The Physician's Workshop

*Bubble Trap for the Helix**

Arterial air embolism remains a definite hazard during extracorporeal circulation and open heart surgery.[1-4] One source of systemic air embolism is the extracorporeal unit. "High flows" increase the possibility that microair bubbles may form and not be effectively removed by the unit before the blood enters into the patient's vascular system. Extracorporeal units have been designed so as to minimize this possibility of air embolism.

We have utilized the DeWall-Zuhdi bubble oxygenator-helix reservoir system and arterial blood flows of 2.2-2.4 liters per square meter of body surface for open heart procedures. Our experience has been most satisfactory. Our confidence has been further heightened by a modification of the helix which effectively diminishes the possibility of air embolism from the apparatus per se. This modification can be termed a "bubble trap" (Figure).



The stainless steel components of the bubble trap are pictured in the upper left corner (Figure I). "C" is a ½" cylinder threaded in the middle ⅓ of its 1.9 cm. length. The cylinder is mounted on a 3.5 cm. diameter disk which is 3 mm. thick and curved to match the curvature of the helix tubing. This curved disk is tapered to its edges so as to fit flush when in place in the helix. The distal side of the ½" cylinder is 3 mm. lower than the proximal side. Direction of flow — left to right.

"B" is a washer with a hole to admit the ½" cylinder of C and curved to match the curvature of C. "A" is a lock nut to hold the tubing of the helix securely between C and B. "D" and "E" of Figure 2 are tools used in the preparation and placement of the bubble trap in the helix. After threading the helix tubing on the Zuhdi coil and marking the bubble trap location 18 cm. from the distal end, the tubing is backed off approxi-

Continued

mately 40 cm. The plastic handle of E (Figure II) is adjusted to the bubble trap mark. A ½" hole is bored with the cork borer D. The tip of the 20 cm. shaft of E is curved and covered with ¼" O.D. x 3/16" wall geon tubing. Component C of the bubble trap is placed on this curved end of E and pushed through the hole in the helix tubing (Figure III). B is now positioned and secured in place with lock nut A. The helix tubing is threaded back on the Zuhdi coil. A 75 cm. length of ½" tubing is fitted on C and secured with a small hose clamp. After priming the helix, the 75 cm. length of ½" tubing is clamped just below the fluid level. The assembled bubble trap is shown in Figure IV.

It is the common experience of those who utilize the DeWall-Zuhdi unit that small, stable bubble patches collect on the blood in the helix. The rate of bubble formation is related to the blood flow and the amount of blood returned to the system via the cardiotomy suction wells. As one to five-millimeter patches, the bubbles migrate slowly toward the lower opening of the helix. The bubble patches rarely migrate to the outflow opening of the helix. If they do, it is unlikely they would be carried out in the arterialized blood, since they float. It is, however, not unreasonable to assume that due to small eddy currents, micro bubbles could be stripped from the main patch and be forced into the outflow stream. The bubble trap stops the bubble patches at a level where it is virtually impossible for this to occur.

The bubble trap, a 75-cm. vertical length of 0.5-inch-diameter tubing, is placed 18 cm. from the outflow end of the helix. The trap is designed to cause a minimum of turbulence in this area of relatively low flow. This low flow results because the cross sectional area of the helix is greater than the arterial line and has considerably less peripheral flow than the flow at the core of the helix.

We have never observed a bubble patch bypassing the bubble trap. On several occasions, as bubble patches have approached the trap, we have observed not only these bubbles but also bubbles not apparently associated with the main patch floating to the surface of the 75-cm. length of 0.5-inch-diameter tubing. We have trapped up to 3 ml. of bubbles in this manner and, therefore, feel the added safety is more than adequate compensation for its use.

Summary

Attached to the DeWall-Zuhdi helix, a single vertical 0.5-inch-diameter tubing has served as an effective bubble trap.

Announcing

EUTRON™

pargyline hydrochloride 25 mg. and methyclothiazide 5 mg.

for control of
moderate to severe
hypertension

Unique combination produces greater antihypertensive effect with lower doses

Eutron is the combination in a single tablet of 25 mg. Eutonyl (pargyline hydrochloride) and 5 mg. Enduron (methyclothiazide). This combination produces greater therapeutic effect than that of either component used alone. Side effects may be milder, too, as dosages are generally lower. The effective dosage is usually one tablet, once daily. Tablets are scored for greater dosage flexibility.

Caution: Federal (U.S.A.) law prohibits dispensing without prescription
100 No. 6812
Tablets (Grooved)
ENDURON™
METHYCLO-THIAZIDE
Caution: Federal (U.S.A.) law prohibits dispensing without prescription

Each Eutron tablet contains two proven antihypertensives in the ratio shown to be most effective in most patients.

TM—TRADEMARK

New **EUTRON** extends your range of treatment in moderate to severe hypertension

A single product you can use even in the presence of congestive heart failure or edema

Eight out of 10 patients respond

In clinical trials, Eutron produced normotension or a significant reduction in blood pressure in eight out of 10 patients studied. The rationale for the product is this: Eutonyl used alone is a potent antihypertensive. Its antihypertensive action is markedly enhanced by Enduron, a potassium-sparing thiazide.[1,2,3] The combination (Eutron) thus produces greater antihypertensive effect with lower dosages of the Eutonyl component, and milder side effects may be seen.

BP reductions in the recumbent and sitting positions often are nearly as great as in the standing. In clinical trials, the average *recumbent* BP reduction was 36/18 mm. Hg.

The average *standing* reduction in clinical trials was 45/22 mm. Hg. Thus the difference between the standing and recumbent readings was only 9/4 mm. Hg.

Significantly lowers blood pressure in all body positions; less likelihood of orthostatic hypotension

In clinical trials, the average reduction in standing blood pressure was 45/22 mm. Hg.; in the sitting position it was 48/20 mm. Hg.; and in the recumbent position, 36/18 mm. Hg.

Because Eutron effectively reduces blood pressure in all body positions, there is reduced likelihood of orthostatic symptoms or hypotension.

This was reflected in the relatively mild character of side effects seen in clinical trials (see below).

Smooth and gradual onset

Onset of antihypertensive action is usually quite smooth. Initial reduction of systolic and diastolic readings is usually seen within a week – maximum reduction in seven to ten days.

Less troublesome side effects may be seen; frequent improvement in "sense of well-being"

Fewer than 1% of patients studied discontinued Eutron therapy because of side effects. This is due in part to the relatively low dosage needed with the combination. Usual recommended dose is one tablet daily—that is, 25 mg. Eutonyl with 5 mg. Enduron. *This is about half the usual therapeutic dose of Eutonyl given alone.* As a consequence side effects may be milder. And, as with Eutonyl given alone, the patient may well note an increased sense of well being. This is in distinct contrast to most other antihypertensive therapy.

ABBOTT

Prescribing information for
EUTRON

INDICATIONS: Eutron (pargyline hydrochloride and methyclothiazide) is indicated in the treatment of patients with moderate to severe hypertension, especially those with severe diastolic hypertension. It is not recommended for use in patients with mild or labile hypertension amenable to therapy with sedatives and/or thiazide diuretics alone.

CONTRAINDICATIONS: Eutron is contraindicated in patients with pheochromocytoma, advanced renal disease, paranoid schizophrenia and hyperthyroidism. Until further experience is gained it cannot be recommended for use in patients with malignant hypertension, children (under 12 years of age), or pregnant patients.

The concomitant use of the following is contraindicated: other monoamine oxidase inhibitors; parenteral forms of reserpine or guanethidine; sympathomimetic drugs; foods high in tyramine such as cheese; imipramine and amitriptyline, or similar antidepressants; methyldopa. A drug-free interval of two weeks should separate therapy and use of these agents.

WARNINGS: Pargyline hydrochloride is a monoamine oxidase inhibitor. Patients should be warned against eating cheese, and using alcohol, proprietary drugs or other medication without the knowledge of the physician. When it is necessary to administer alcohol, narcotics (notably meperidine), antihistamines, anesthetics, barbiturates and other hypnotics, sedatives, tranquilizers, or caffeine, these agents can be used cautiously at a dosage of ¼ to ⅕ the usual amount. Avoid parenteral administration where possible. Withdraw pargyline two weeks before elective surgery.

Patients should be warned about the possibility of postural orthostatic hypotension. Those with angina or other evidence of coronary disease should not increase physical activity. Pargyline may lower blood sugar. Potassium depletion is unlikely at the recommended dosage, but if it occurs, adjust dosage or withdraw or provide added natural food sources of potassium; potassium tablets should be avoided wherever possible, as bleeding or obstructive ulceration of the small bowel has been associated with their use; potassium levels should be especially watched if the patient is on digitalis or steroids, or if hepatic coma is impending.

PRECAUTIONS: When determining the antihypertensive effect of Eutron, blood pressure should be measured while the patient is *standing*. Use with caution in hyperactive or hyperexcitable persons. Such persons may show increased restlessness and agitation. Withdraw drug during acute febrile illness. Watch patients with impaired renal function for increasing drug effects or elevation of BUN and other evidence of progressive renal failure; withdraw drug if such alterations persist and progress. Pargyline has not been shown to cause damage to body organs or systems. As with all new drugs, complete blood counts, urinalyses, and liver function tests should be performed periodically. The drug should be used with caution in patients with liver dysfunction. With prolonged therapy, examine patients for change in color perception, visual fields, and fundi.

Elevated blood urea nitrogen, serum uric acid or blood sugar are possibilities attributable to the methyclothiazide in Eutron. Methyclothiazide may also reduce arterial response to pressor amines. Blood dyscrasias, including thrombocytopemia with purpura, agranulocytosis and aplastic anemia, have been seen with thiazide drugs.

SIDE EFFECTS: The use of pargyline may be associated with orthostatic hypotension. Mild constipation, slight edema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence, delayed ejaculation, rash, and purpura have been encountered with pargyline. Hyperexcitability, increased neuromuscular activity (muscle twitching) and other extra-pyramidal symptoms have been reported. Drug fever is extremely rare. Congestive heart failure has been reported in a few patients with reduced cardiac reserve. Nocturia has been observed with the combination. If side effects persist, despite symptomatic therapy or reduction of the dose, discontinue the drug.

Book Reviews

Some books are to be tasted, others to be swallowed, and some few to be chewed and digested. — Bacon

MODERN TREATMENT — **Vol. 2, No. 4, July 1965, Harper and Row.**

This issue concerns the treatment of Diabetes Mellitus and the Emergency Treatment of Trauma. Both sections are well written. The section on diabetes is detailed enough so that it is valuable as a reference, whereas the section on trauma, covering such a large subject, is less detailed. A general discussion of fractures is not included.

The issue (a bimonthly publication) is paper bound and suitable for browsing and review.

Harrison H. Farley, M.D.

A PRIMER OF WATER, ELECTROLYTE AND ACID BASE SYNDROMES, **3rd edition — Emanuel Goldberger, Lea and Febiger, 1965, 410 pages.**

This is a revised edition of a book which has been well received by clinicians. Diagnostic and therapeutic considerations in management of the disorders of water, electrolyte and acid base in patients are presented. Although the text does not go into great detail on the physiologic considerations in these disorders, enough is presented to make the clinical problems understandable, both as to manifestations and their management.

I found the book well written, clear in its presentation and extremely useful in its application to clinical problems. It is recommended as a very practical and quick reference text for the clinician.

Alvin L. Schultz, M.D.

SYNOPSIS OF CARDIOLOGY — **W. I. Gefter, B. H. Pastor, R. M. Myerson, C. V. Mosby Co., St. Louis, Missouri, 1965. 839 pages; price $9.85.**

A simple classification of medical books is this trichotomy: big, thick texts for medical students; large thin monographs for specialists; and small, pocket-sized books for house staff. **Synopsis Of Cardiology** measures 5 by 8 inches, and its 800 odd pages will form a respectable bulge in the pocket of the interne on medicine, who, I suspect is the target at whom the author aimed in his preparation of this synopsis. There are six sections covering the cardiovascular examination, heart failure, arrhythmias, types of heart disease, diseases of the vascular system, and special problems. The section on cardiovascular examination includes an excellent resume of electrocardiography and cardiac roentgenology. It is surprising that chapters on cardiac catheterization and angiocardiography, so essential in present day cardiovascular studies, are omitted.

The discussion of types of cardiac disease and their treatment is uniformly good. Pastor, who contributes some excellent chapters, emphasizes the value of "bloodless" phlebotomy, rotating tourniquets in severe heart failure. He also mentions many helpful measures to be undertaken in intractable failure. As for venesection in heart failure, he would use it in congestive heart failure associated with polycythemia, that is, perhaps only once in a lifetime of cardiological practice. But this would shelve a useful tool in the treatment of acute heart failure, especially acute pulmonary edema, when venesection can be lifesaving (as is elsewhere stated in the book).

Reuben Berman, M.D.
Minneapolis, Minnesota

ANATOMY AND SURGICAL TECHNIQUE OF GROIN DISSECTION — **Shieber and Dillard, C. V. Mosby Company, St. Louis. Price $9.75, 97 pages, 36 illustrations.**

Groin dissection is indicated in malignancies of the vulva, anus, penis, and of the lower extremities. Almost the only exception would be extremely small lesions of the vulva, small epidermoid carcinomas arising from burn scars, osteomyelitis, or stasis ulcers, and small lesions of the anal canal. A clarification of these exceptions is detailed in the monograph.

The technique of the procedure is reasonably well illustrated with wash type drawings; and for the surgeon who would be attempting to view this procedure, the illustrations are sufficiently adequate.

This well bound monograph is worth possessing.

Gleanings from the Meetings

Minnesota Surgical Society
November 5, 1965
Minneapolis, Minnesota

The Minnesota Surgical Society met for its semi-annual meeting on November 5, 1965. Dr. William ReMine, President, and Dr. Stuart W. Arhelger, Program Chairman, had arranged an excellent series of scientific papers.

Zollinger-Ellison Syndrome

The guest speaker, Dr. Stanley R. Friesen, Professor of Surgery at the University of Kansas Medical School, delivered the main address of the session on the subject "Evolution of Diagnosis and Management of the Zollinger-Ellison Syndrome,"* In addition to the usual hypersecretion and recurrent ulceration, several identifying features were noted as suggestive or diagnostic of the disorder. He found common occurrence of hyperrugation** in the stomach or in a residual pouch, gross nodularity of the duodenum, steatorrhea, and 12-hour gastric secretion of at least one liter containing more than 100 mEq/L of hydrochloric acid. Only occasionally was he unable to find the primary lesion in the pancreas despite the presence of metastatic lymph nodes and other areas of metastasis. Chemical analysis revealed a gastrin-like substance from the tumor of all but one of the cases.

He found that a total gastrectomy controlled the disease, and even in the presence of metastases the removal of the target organ effectively prolonged life for several years.

Portacaval Shunt

Dr. Martin A. Adson presented his experience with emergency portacaval shunt for bleeding esophageal varices. Very commendable mortality figures were presented, even though some patients with encephalopathy and some with intense jaundice were included in his series. Adson makes the point that jaundice in the alcoholic cirrhotic greatly increases surgical risk, whereas this is not necessarily true in the cholestatic jaundice of posthepatitic or biliary cirrhosis. A direct portacaval shunt is preferred in the emergency situation. However, splenorenal shunts, elected for technical reasons, also controlled hemorrhage from varices.

Aorta-jejunal Fistula

Dr. Richard E. Larson presented a rather astounding case of upper

*See Minnesota Med 46:864, 1963.

**See Test Your Word Score Page 271.

Continued

gastrointestinal bleeding due to aorta-jejunal fistula. The fistula had developed at the upper end of a nylon prosthesis which had been implanted five years previously. This complication was technically controlled by inserting a new bifurcation prosthesis and oversewing the proximal end of the old graft just distal to the fistula. This was again followed in a few months with recurrences of gastrointestinal bleeding from reestablishment of a fistula originating from the distal end of the old graft which had not been removed. He makes the point from this recurrent episode that, in spite of the technical difficulties, further degeneration of the remaining old graft can lead again to such difficulties, and he therefore recommends removal and replacement rather than closure and bypass.

Operation for Hypercholesterolemia

Dr. Henry Buchwald, Department of Surgery, University of Minnesota Medical School Hospitals, won the first annual prize essay and presented his paper on the development of the ileal bypass operation as a potential therapeutic procedure in patients with hypercholesterolemia. The initial experimental studies were done in the rabbit and then in the pig, in order to test the thesis that cholesterol absorption occurs mainly in the ileum, and that if this area is bypassed, cholesterol absorption and secondary blood cholesterol could be reduced.

A blind loop of ileum about one third of the small intestine is produced and an end to side anastamosis of the proximal end of the ileum is made to the cecum. The first case was done two and a half years ago. Nineteen human cases have been done to the present time. These patients have some diarrhea initially but by three months have one to three stools per day, and have had no weight loss. They require Vitamin B_{12} parenterally every two months. Blood cholesterol levels have been reduced to normal or below (an average of 40%). Further studies are being conducted to ascertain clinical effectiveness and, in fact, the feasibility in the management of these patients.

Theoretical to Empirical

Until probably sometime during the thirteenth century, the anatomy that was taught to students of medicine was entirely of a theoretical nature, and what was worse, the theories themselves were often quite erroneous. It is believed that the practice of dissection of human bodies for classes in anatomy was started very likely sometime during the thirteenth century. However, it was not until several hundreds of years later that the student did any dissection himself. And even then there were often only two bodies to be dissected in a medical school during a school year. In the early days, the teacher lectured while sitting at his desk as a barber did the dissecting, and a demonstrator pointed out the various structures with a wand. It actually was a couple hundred years before the teacher had acquired enough energy to get off of his fanny and stand beside the cadaver to point out the structures himself.

Forensic Psychiatry

M. ROBERT WILSON, JR., M.D.*
Rochester, Minnesota

SINCE MAN first formulated the principle of culpability — and its corollaries: punishment and deterrence — the concept of criminal responsibility has stimulated controversy, has provoked hostilities, schisms and revolutions, and has generated countless learned volumes. At present, psychiatry finds itself designated as the heir to the issue of this forced marriage of theology and jurisprudence. Before considering the duties, hazards, and consequences of such guardianship, it is useful to look at the evolution of this concept.

Evolution of Forensic Psychiatry

Those cradles of democracy, the Greek city states, were among the earliest civilizations to give legal recognition to the mitigating role man's passions and emotions should be accorded in the judicial process. Elaborate provisions to protect the emotionally disturbed from being punished for their misbehavior were incorporated into Plato's laws for a model society.

Doctrine of "Fatal Necessity"

Pesidonius the Stoic postulated a doctrine that closely parallels the contemporary concept of irresistible impulse; he designated it "fatal necessity" and frequently invoked it with success as a defense on behalf of his clients, further testimony to the cognizance of the importance ascribed to emotions in the delicate function of assessing responsibility in those early days.

The Elimination of Humanistic View

It is not surprising that, in the ensuing Dark Ages, one of the first virtues of that earlier democratic heritage to be eliminated was just this very humanistic view of responsibility, guilt, and punishment. In 429 A.D., a document titled the Codex Theodosinus proclaimed by fiat that magic was bad and criminal and that practice of it was illegal; the fatuous conclusion that insanity was both the cause and the consequence of sorcery was inevitable and forced the physician into abdicating his traditional role of healing men's minds as well as their bodies, leaving the former to the Church and the State. This persecution of the insane as willing agents for the legion of devils which invaded Christendom reached its height in the fifteenth century with the publication of *Malleus Maleficarum,* or *Witches Hammer,* by two friars, Henry Kramer and James Sprenger. In their monumental work these

Continued

zealous and scholarly ecclesiastics outlined the magnitude of the witchcraft problem, gave case reports of known instances of transvection and other equally deplorable manifestations of demonology, and prescribed the only satisfactory route to salvation: freeing the soul by destroying by fire its defamed tabernacle. The resistance to this radical text was widespread but was soon quieted when Pope Innocent VIII gave moral sanction and papal license to the friars' work in 1484.

Sick Minds the Bailiwick of Medicine

The effect of *Malleus Maleficarum* on the continuing exclusion of psychiatry from the forum of assessing human behavior was somewhat tangential to the main historic issues, but a survey of pertinent chronicles reveals that a few scientific voices were raised in an effort to return sick minds to the bailiwick of medicine. Johann Weyer, who lived from 1515 to 1588, was the most persistent and articulate of these, and he has been cited as the first truly humanistic medicolegal psychiatrist. Weyer wrote ardently and was intrepid in the exposition of his view that witches were sick people and should be turned over to physicians for care. He asserted that the confessions of accused witches and sorcerers were themselves a form of madness and that this behavior was hardly an expression of free will but, quite the contrary, was a form of illness. This was a view which no one would freely embrace. For his efforts he earned the distinction of having the titles of his books listed on the Catholic Index and escaped excommunication only through his otherwise exemplary adherence to church dogma. Among his lay antagonists the most vitriolic was Jean Bodin, an attorney, who issued an extensive rebuttal of Weyer's views. He claimed that a physician should not be allowed to trespass into the sanctuary of the courts, and he was widely supported by most of his colleagues. "If Weyer's sophisms . . . held good, the thieves and robbers might always appeal for mercy by blaming the devils for their deeds . . ."[1] reads one passage which characterizes much of Bodin's argument.

Faced thus with certain censure and calumny, few of Weyer's colleagues dared support him, and some indeed even denounced him; the views that Weyer espoused died with him and remained dormant for nearly a century. The succeeding chapters in the chronicle of the role insanity should play in tempering the assigning of responsibility were written in Great Britain, where a judiciary unfettered by the influences of Kramer and Sprenger was slowly deliberating the question of a humanistic application of the law. In the early part of the seventeenth century the English jurist, Lord Hale, ruled that the existence of insanity was a valid defense in considerations of responsibility for criminal acts, but he devoted his attention to the concept of partial insanity, it being his allegation that the latter is not an adequate defense. For Lord Hale, the accused must have been stark raving mad at the time of the crime to be exculpated; anything short of this was insufficient. Few persons were acquitted. Lord Hale's views served as precedent throughout England for nearly 200 years.

Hadfield Decision: The Beginning of Forensic Psychiatry

In 1800, the trial of a man named Hadfield, charged with shooting at King George III in London's Drury Lane Theatre, marked a significant milestone for forensic psychiatry. The defense counsel, Mr. Erskine, defined for the jury, for the first time in an English court of law, the concept of delusional thinking; he argued that his client had fired on the sovereign as a consequence of such a delusion, and he won for him an acquittal. This was, however, not the dawn of enlightenment that it should have been. In 1812, another man, Bellingham, was found guilty of murder (of the Hon. Spencer Perceval) even though his counsel clearly showed that he was delusional. In his charge to the jury, the Lord Chief Justice ignored the Hadfield decision and emphasized the issue of cognition as a test for insanity — that is, did the defendant know right from wrong. These knowledge tests, based on the Bellingham decision, won widespread acceptance and constituted the prevailing English view on the matter of insanity for several decades.

What Is Insanity

In the nineteenth century a chorus of voices was heard tardily promoting the views of Johann Weyer. In France, Pinel endeavored to show that intellect was not the sole decisive factor governing man's behavior, and Esquirol wrote a treatise establishing that insanity can exist without concurrent delirium. Tuke proposed the concept of inhibitory insanity, which asserted that all madness was a consequence of decreased inhibition in one sphere or another of the mind. Prichard described "moral insanity," and other physicians in England, in Europe, and in the United States attempted to point out that the prevailing concept of cognitive tests was not adequate to establish or refute the existence of insanity. The furor surrounding the whole issue of insanity finally compelled the English House of Lords, in 1843, to examine the situation and, hopefully, clarify it.

The McNaughton Rule

In that year there occurred the celebrated trial of a Scotchman, David McNaughton, who was charged with murder (of a man named Drummond, private secretary to Sir Robert Peel, the Prime Minister). McNaughton harbored delusional beliefs that he was being persecuted by the Prime Minister and killed Drummond by mistake. The trial judge, in his charge to the jury, acceded to defense counsel's claims and supported the view that McNaughton was insane, outlining a test for insanity which has since been referred to as the McNaughton rule. The accused was acquitted of the charge, which generated heated controversy. One view was most acridly stated by the queen, Victoria, who allegedly remarked that anyone who wanted to kill Sir Robert could hardly be judged insane. In their investigation, the Lords approved the test in McNaughton's case and recommended that it become established precedent for future cases. In its approved version, the McNaughton rule states the following:[2] "To establish a defense on the ground of insanity, it must be clearly proved that, at the time of committing the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or, if he did know it . . . he did not know he was doing what was wrong." The Lords added that the question of right and wrong should be put in reference to the particular act with which the accused is charged.

The McNaughton rule thus incorporated both the cognition test and a principle which went beyond mere knowledge of right and wrong. This too represented an unsatisfactory ultimate solution to the problem of criminal responsibility, but it did effectively bring some consistency to the common law on the subject. Dr. Isaac Ray, prominent American psychiatrist, was among the many critics of the McNaughton rule; in his book *Medical Jurisprudence of Insanity* (1871),[3] he lamented the efforts by jurists to identify the *sine qua non* of mental illness and urged them to accept the concept of insanity as a disease which, in consort with other distempers, requires the application of many tests by specialists to effect an accurate diagnosis. Rather than heeding this advice, the jurists continued their search for a pathognomonic test to ascertain the presence or absence of insanity.

Irresistible Impulse

Shortly after the publication of Ray's second edition, Shaw (Chief Justice of Massachusetts) and Gibson (Chief Justice of Pennsylvania) dusted off Pesidonius' long-dormant doctrine of fatal necessity, christened it "irresistible impulse," and sought for general endorsement of it as that *sine qua non* whose very existence Ray had labeled chimeric. "Irresistible impulse" did win a limited acceptance, and in some jurisdictions it was added to the McNaughton rule as a footnote; at the present time it is incorporated into the legal codes of 17 states and has been accepted by the United States Supreme Court.

Shortcomings of McNaughton Rule

The McNaughton rule clearly limits testi-

Continued

mony to certain specific features of mental illness, and, since consideration of other features which we all recognize as pertinent in the assay of insanity is in violation of the rule, the psychiatrist testifying in such a jurisdiction will be hampered in his attempt to describe for the jury the mental status of the accused. The inevitable consequence of this is that certain mentally ill persons will be found culpable and sentenced or even executed for acts which were a product of their illness and for which they should not be held responsible.

An instance of the use and abuse of psychiatry in a murder case was reported by Wiseman.[4] The defendant, who was accused of murdering his fiancée, was clearly psychotic, but defense testimony to the pertinent psychologic issues was precluded because of the McNaughton rule, while the use of psychiatric expertise by the prosecution within the scope of the rule left no choice for the jury but to find the defendant guilty. Even the prosecutor supported the family's appeal for gubernatorial clemency, recognizing in fact the accused's derangement; however, the defendant committed suicide in jail, affording graphic but tragic evidence for the validity of his defense, but obviating action on the plea.

The Durham Decision

Not all jurists ignored Ray's supplications; in New Hampshire in 1871, Judge Charles Doe presaged a broader and more sophisticated concept of insanity than had heretofore ever been espoused in a court of law when he charged a jury (in the case of State of New Hampshire vs. Jones) with the simple admonition that the defendant could not be found guilty of the murder of his wife if his act was the product of mental disease. Judge Doe incisively avoided prescribing tests based on one, two, or three mental functions and paid homage to the mosaic of man's mind, the loss of any piece of which can spoil the whole and of which no piece is endowed with superior status over another. But few jurisdictions accepted Judge Doe's farsighted philosophy.

In 1954, however, a far-reaching doctrine was postulated by Judge Bazelon of the United States Court of Appeals for Washington, D.C. In the trial of a man named Durham (for breaking and entering) because of a history of frequent past offenses which had led to acquittals based on insanity with subsequent commitments to a mental hospital, testimony to his chronic recidivism was allowed by the trial judge and accepted as good and adequate reason that insanity could not be permitted again as a defense. Durham was then found guilty. His appeal was heard by Judge Bazelon who ruled that an accused is not criminally responsible if his unlawful act was the product of mental illness or defect. This ruling has been called the Durham decision and has, in the past decade, along with the McNaughton rule and "irresistible impulse," composed American jurisprudence concerning insanity as a defense.

Allowing Discussion of Mental Illness

The spate of arguments concerning the Durham decision bespeaks the controversy that it has generated, and, in subsequent rulings, numerous efforts have been made to temper its implications. Certainly, this decision removed the fetters from psychiatric testimony by allowing discussion of mental illness without reference to any particular facet.

Prosecution Must Prove Sanity If It Is In Doubt

In fact, carried to its ultimate evolution, it switches the burden of proof from defense to prosecution, making it incumbent on the latter to establish the presence of sanity when this question is raised by the defense. Such a doubt can be introduced into almost any case with a minimum of effort. As meritorious as this decision is, praise must be tempered with a consideration of the total implication inherent in this precedent. Did Bazelon, as many of his detractors allege, throw out the baby with the bath water; does the Durham decision exculpate, by definition, our entire criminal population? Glueck,[2] in the Isaac Ray Lectures at Tulane University in 1961, presented an assessment of some of the more salient criticisms of the Durham decision.

Shortcomings of Durham Decision

The Durham decision has been attacked as being too vague in not providing the jury with explicit guides to the determination of insanity, whereas the McNaughton rule and the "irresistible impulse" concept furnish rigid formulae. In this sense the Durham decision clearly respects the complexity of mental illness and, while taxing the capacity of the juror to comprehend this, it does service to the cause of justice.

It has been attacked as a menace to law enforcement; its critics claim that it will permit the acquittal of any accused lawbreaker. However, the facts are that, while the number of pleas of insanity has increased sharply in the jurisdictions accepting the Durham decision, the percentage of acquittals has not.

It has been attacked as effecting a reduction in the deterrent value of punishment. Many behavioral scientists doubt the validity of the concept that punishment for wrongdoing carries with it any inherent deterrent value. Many sociologists and psychologists argue that deterrency is inculcated into the individual through such agencies as family, society in general, and religion and thus is a feature of the superego which is not vulnerable to the influences of specific statutes.

It has been attacked by the moralists who see it as a contradiction to the concept of free will; this is clearly a twentieth century echo of Bodin's thesis (promulgated as a refutation of Johann Weyer).

Mens Rea and Actus Reus

Most students of law and of psychiatry, however, consider the primary shortcoming of the Durham decision to be the intangible link between act and disease or defect of mind, a relationship which must be such that the former can be clearly established as a consequence of the latter. The law has traditionally exacted fulfillment of the requirements of *mens rea* (state of mind which could lead in a rational fashion to the alleged criminal action) and *actus reus* (the establishment of the fact that a criminal act has been committed) before a person can be indicted for a crime, a step preliminary to prosecution and trial.

The Durham decision—as do all tests of insanity—concerns itself with the nature of the *mens rea,* accepting the causal link between intent and act once an indictment has been entered. It does not ask whether or not the act was a product of the mind of the accused; this has already been asked and answered affirmatively. It asks whether or not the act was a product of the diseased mind of the accused, once the fact has been established that the accused does indeed possess a diseased or defective mind. This so-called disease-product test, first proposed by Judge Doe in 1871 and later adopted by Judge Bazelon and the District of Columbia Circuit Court of Appeals in the 1954 Durham decision, has in fact been rejected by every other court (as of 1961) which has considered it. The reasons for its rejection arise quite clearly and consistently from the fear that accepting it will be a blow to the premise of free will. A prominent jurist has said that all law in western civilization is directed by a strong common sense which assumes the existence of freedom of the will as a working hypothesis in the solution of legal problems.

Concept of "Disease Product"— Carter vs. U. S.

The District of Columbia Circuit Court of Appeals in subsequent decisions tried to clarify the concept of "disease-product" and correct its shortcomings. In Carter vs. the United States,[5] this court said in 1957:

The basic import of the criminal law is punishment for a vicious will which motivates the criminal act. The defendant is not to be found guilty as charged unless it is established beyond a reasonable doubt that when he commits the act, first, that he understood and appreciated that the act was a violation of law; and second, that he had the capacity to exercise his will and to choose not to do it. If, because of some abnormal mental condition, either of these elements is lacking, he cannot be found guilty. To hold

Continued

him guilty the jury must find, beyond a reasonable doubt, both that he understood and appreciated the act charged was a violation of law, and that he possessed the capacity and competence to choose to do it or refrain from doing it.

The Carter decision thus gives new impetus to the cognitive test while emphasizing as well the role of will; yet, it does not restrict psychiatric testimony regarding an alleged mental disease which might interfere with either. Other decisions by this court further modified and molded the Durham decision; these included decisions which explored the diverse manifestations of mental illness, in relation to admissibility in evidence, as well as the disease-product dilemma.

The Durham decision assumed that mental disease can produce criminal acts, and, indeed, psychiatrists as well as jurists are divided on this issue. Roche[6] stated that "the idea that mental illness causes one to commit a crime has an unmistakable lineage from demonology." Szasz[7] said that "the very occurrence of almost any crime today functions as a powerful impetus for the creation of a theory to explain it."

Medical View and Legal View Irreconcilable

It now is plain that the Durham decision did not serve as a panacea for the age-old problem of forensic psychiatry. If neither decisions based on the McNaughton rule, which pay homage to a pathognomonic sign of mental illness, nor those based on the Durham decision, which raise imponderable considerations of free will, solve the dilemma of justly and fairly ascribing criminal responsibility when mental illness is at issue, where then does the solution lie? There are those who argue that the medical view of mental illness and the legal view of insanity will always be irrevocably irreconcilable.

Fundamental Changes Required

The solution would seem to require two quite fundamental changes in the basic philosophy and practice of our judiciary system, sidestepping the issue of semantics altogether.[2]

Determine Guilt & Punishment

The first change is separating the dual functions with which the trial is endowed: namely, determining guilt and levying punishment.

Determine Insanity

The second change, in essence a corollary to the first, is recognizing the impossible responsibility with which a group of 12 laymen is charged: to assimilate, integrate, and weigh the psychiatric evidence in an effort to decide whether the accused is or is not insane.

It would seem that we are expecting too much when we ask these 12 persons to render a medical judgment over which psychiatric experts are in disagreement in any given trial. Promulgating these changes would have the effect then of reserving to the trial judge and jury the responsibility and duty of ascertaining whether the accused did or did not commit the unlawful act as charged. If the trial phase finds the defendant guilty of committing the act, and if insanity is raised by the defense as a mitigating circumstance, then the role of insanity in determining the commission of the act should be decided by a post-trial hearing, after which sentencing or treatment would be undertaken.

Psychiatric testimony would then be removed from an adversary setting and confined to the post-trial phase. Ideally, this testimony would be weighed by a panel of experts, including a jurist, a psychiatrist, and others of professional training in the behavioral sciences. Psychiatric testimony would be based on an objective evaluation of the accused following his trial; sentencing or treatment would be prescribed accordingly after the public sentiment had waned and the demand for retributive punishment attenuated. Finally, the issue of insanity would be pre-empted from the jury forum.

Pre-trial Psychiatric Examination

There have been two recent efforts to alleviate the plight of forensic psychiatry. In

Massachusetts the so-called Briggs law provides for an automatic pre-trial psychiatric examination of all persons who are indicted for a capital crime, of all persons who have been indicted previously, and of all persons who have been previously convicted of a felony.

Mentally Ill Exempt from Trial

The theory of pre-trial evaluation is based on the aim of removing psychiatric testimony from the jury forum. On the basis of such examinations, persons who are mentally ill would be exempt from trial, and a treatment tribunal would advise the court regarding commitment proceedings. In this case, however, the person still would not have had his day in court relative to the charge brought against him and, in the event of recovery, he would be liable for trial and sentencing.

Inability to Appreciate Criminality

The other effort was by the American Law Institute[2] in 1962, which advocated a model penal code which states that "a person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect, he lacks substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirement of the law." To this is appended a caveat to the psychopath: the code specifically excludes antisocial character disorders from the meaning of mental disease or defect.

Legal Treatment of Criminally Insane

The concept of acquittal by reason of insanity brings up the controversial issue of treatment. In some jurisdictions—notably Massachusetts—when the charge from which the defendant has been so acquitted is homicide, the law decrees that the individual be automatically incarcerated in a state hospital for life, the only authority for dismissal being vested in the governor. Many other jurisdictions have incorporated into their penal codes mandatory hospital sentences, and it is not uncommon to find a more lenient penitentiary term prescribed for a given offense than would be the corresponding statutory hospitalization. These statutes suggest that there are hidden overtones of retribution and deterrence dictating the courts' actions and the legislatures' whims which established them. More liberal laws prescribe that release from the hospital of a person acquitted by reason of insanity should be based on the patient's ability to prove, beyond a reasonable doubt, that he will not be dangerous to others within the forseeable future; this proof can be based on the testimony of a hospital physician in a court hearing.

Concern for the rights of the individual should be paramount in instances of mandatory hospitalization. The traditional right of habeas corpus receives special treatment in some states where proceedings leading to habeas corpus make it incumbent on the patient to establish, beyond a reasonable doubt, that the hospital superintendent has acted arbitrarily and capriciously in refusing to certify the patient to district court for discharge. In such actions, this places a far greater burden on the appellant than he must bear in criminal proceedings. Szasz, together with many others, deplored the transformation of mental hospitals into surrogate prisons, and this issue promises to generate considerably more debate in the years ahead.

To make prisons into hospitals, hospitals into better hospitals, and judicial forums into treatment tribunals while preserving the liberty of the individual from further compromise is a Herculean task, the impediments against which are succintly articulated in this paragraph from Zilboorg and Henry.[1]

"It is fundamentally not so much the struggle for the humane recognition of the criminal's psychopathological shortcomings and the insane individual's human needs, as it is a struggle for that enlightenment without which the average man is unable to cease being afraid of the lawbreaker and the lunatic. As long as this deep-seated fear persists, the criminal and the insane are bound to be treated with that harshness and neglect which does not permit public opinion to com-

Papyrus Ebers[*]

For Burns

For burns the ancient Egyptians had a number of remedies, the simplicity of which belied their startling ingredients: the hair of a cat, a portion-of-cake, the head of an electric eel, etc. However, a five-day series of surefire remedies was preferred.

Against Burns: To Use on the First Day

Black amat-juice
Put thereto.

Another on the First Day

Elderberries
uah-corn
Cat's dung
Mix into one in Cake-water and apply thereto.

To Use on the Second Day

Goat's dung
Burn, crush, rub in Yeast-that-is-fermenting, and put thereto.

To Use on the Third Day

Thorns-of-Acanthus, dried
Crush them in cooked durra-corn and Onions, put in Oil, and apply as a plaster.

To Use on the Fourth Day

Wax
Roasted Cow's Fat
Palm-fibres
Make into one in uah-corn, and apply as a plaster.

To Use on the Fifth Day

Onions
Red-lead
Fruit-of-the-am-tree

Crush, rub in Copper-splinters, make into one and apply as a plaster.[**] Should the burn prove too stubborn to yield to such heroic measures, the gods were invoked for reinforcements.

Incantation for a Burn

'O son, Horus! There is Fire in the Land! Water is not there and thou art not there! Bring Water over the River-bank to quench the Fire.' To be spoken over Milk-of-a-Woman-who-has-borne-a-Son.[**]

Perinatal Mortality Study

Erythroblastosis Fetalis

This was the fourth pregnancy of this 30-year-old Rh negative mother. Her first child was full term and normal. Her second child was born three weeks prematurely and died at age three hours from erythroblastosis fetalis. Her third child was a macerated stillborn at 5½ months' gestation. During the present pregnancy, the mother had one Rh titre determination at 33 weeks of gestation, which was reported as "low titre." Fetal heart tones were present during the mother's prenatal visit at 36 weeks, but were absent when the mother was admitted to the hospital after going into labor at 38 weeks. She delivered a 7 lb., 6 oz. stillborn infant. The size and condition of the placenta was not noted. Autopsy on the infant revealed considerable edema of all extremities, along with hepatosplenomegaly and microscopic changes consistent with the diagnosis of erythroblastosis fetalis. Rh studies on the mother's blood following delivery revealed sensitization to the C and D factors.

Comment

The Perinatal Mortality Study Committee criticizes the care that this mother received, particularly with her past history of delivering a child dying of erythroblastosis fetalis, followed by a delivery of a macerated stillborn. The mother should have had repeat Rh titres during the pregnancy to check for a rising titre; although even a low Rh titre may often be associated with a severely involved erythroblastotic infant. The Rh titre cannot be relied upon to indicate whether or not or how severely the infant may be affected with erythroblastosis. Some hospitals have facilities for amniocentesis, which is performed at 30 to 32 weeks and repeated at 34 to 36 weeks of gestation. Bowman and Pollock[1] present a good review of amniocentesis. Amniocentesis gives a reliable estimate of how severely the infant is affected with erythroblastosis, and whether or not to induce premature labor.

In the present case, even in the absence of amniocentesis, the mother should have had induction of labor at 36 weeks of gestation because of the erythroblastosis in her previous pregnancies.

The Perinatal Mortality Study Committee will continue to study perinatal deaths to find factors which could be favorably controlled, thus improving the care given to mothers and their infants.

Case 2

The mother of this infant was 21 years old, Rh negative, and this was her fourth pregnancy. Her first infant was normal. Her second pregnancy resulted in twins born six weeks prematurely, both of whom required an exchange transfusion because of erythroblastosis. Both twins lived. The mother's third pregnancy resulted in a jaundiced stillborn at eight months of gestation.

During the present pregnancy, the mother had no Rh titre determinations and no attempt at early induction of labor. At 38 weeks of gestation she had spontaneous labor. Fetal heart tones were not heard during the 11-hour labor. The mother gave

Continued

birth to an eight pound, one ounce extremely edematous infant that had petechiae, particularly over the face. The presentation was left occiput posterior. The infant was given oxygen and made several attempts to breathe but expired at three minutes of age. Cord blood was Rh positive and Coombs positive. No autopsy was done on the infant. The placenta measured 26 by 16 cm. and was consistent with erythroblastosis.

Comment

The Perinatal Mortality Study Committee criticizes the care that this mother received during pregnancy. Reference is made to a recent article in "The New England Journal of Medicine" which criticizes a perinatal death due to erythroblastosis fetalis.[1]

The Committee makes the following criticisms:

1. The mother should have had serial Rh titres done during the pregnancy. Some hospitals also have facilities for amniocentesis[2] which should be done at about 30 weeks of gestation and repeated at 34 weeks of gestation.
2. With the history of erythroblastosis in the second pregnancy, followed by an erythroblastotic stillborn in the third pregnancy, the mother should have had early delivery in her present pregnancy, perhaps as early as the 36th week of gestation. Rh negative blood compatible with the mother's blood should be available before delivery. The blood may be needed for an exchange transfusion immediately after delivery. It is inexcusable not to determine the severity of the disease and attempt to terminate pregnancy early for the mother in this case.

The Committee will continue to study perinatal deaths to elucidate preventable factors. Only by improving the prenatal care of Rh negative sensitized mothers can we as physicians hope to salvage more of the infants resulting from these pregnancies.

Economy is going without something you do want in case you should, some day, want something which you probably won't want. — Anthony Hope Hawkins

History of Medicine

Rudolf Ludwig Karl Virchow

(1821-1902)

"Omnis Cellula E Cellula"

Rudolf Virchow's DIE CELLULARPATHOLOGIE was published in 1858,, nearly a century and a decade ago. Yet today this dictum: OMNIS CELLULA E CELLULA remains entirely valid.

Writing in his Archiv in 1877, thirty years after the founding of his periodical, Virchow speaks in retrospect as well as precognition. . . "As a result of daily observation, the heretical thought of the continual reproduction of cells within the individual gradually germinated and grew. These thoughts became the basis of cellular pathology.

What we should have learned, in the period of a generation which lies behind us, is above all the realization that pathology must be an independent science. . . One should remain aware that this emancipation of pathology, this elevation of pathology to the rank of a natural science, requires before all else that pathologists guard their independence, that they permit no strange science to introduce its hypotheses into pathology at will, in order to prevent it from again being pushed back to the position of a mere applied science."[1]

Born in Schivelbin, Pomerania, one of the northeastern German provinces, Virchow was well grounded in ancient and modern languages at an early age. Entering Coeslin Gymnasium at the age of fourteen he pursued Latin, Greek, Hebrew, and Italian. By the time he matriculated at the University of Berlin at the age of eighteen, he was an accomplished linguist. At a result of this early training, Virchow was a skillful glossologist, being a master of exactness in his choice of words and terminology. At the University he developed a deep interest in the basic concepts of natural science. Graduating in 1843, he was appointed assistant prosector at the Charite Hospital, working under Robert Froriep. There . . . "in addition to dissecting dead bodies, he cultivated industriously two studies that in his far seeing judgment were to rejuvenate pathology, microscopic study of tissues and analytical chemistry."[2]

In 1846 he became prosector of the hospital. Soon after this he joined the teaching staff of the University. Associating himself with two outstanding pathologists of the day, Benno Reinhardt and Ludwig Traube, . . . "they did experimental work at that early period on tuberculosis of the lung as influenced by section of the vagus. The remarkable thing about this promising phase of his productive life is not, as Becher* writes, so much that he made original discoveries in leukemia, thrombosis, embolism, and so forth, but rather that he introduced new methods of research, namely, experimental pathologic study."[3] In 1847 Reinhardt and Virchow produced their own journal. "This was a move of outstanding importance. The journal met a hearty reception from the medical profession as filling an obvious need, and has remained the leading journal of pathological anatomy to the present time. With Reinhardt's untimely death it passed into the exclusive editorial control of Virchow and has since been known by the simple abbreviation 'Virchow's Archiv.' "[4]

---

*Becher, W.: Rudolf Virchow, Eine biographische Studie, Karger, 1891.

Continued

Another consuming and life-long interest of Virchow, aside from his study of pathology was the study of economic and social problems. In 1848 he was appointed a member of a commission to investigate an epidemic of typhus fever in Silesia. His report of conditions there as he found them revealed deplorable social conditions along with revolutionary recommendations for their correction. The Government in power felt he was too democratic, so he was gradually relieved of his prosectorship at the Charite.

Aneurysms

Aneurysms occur in every part of the body, but especially beside the windpipe, in the formation of the so-called aneurysmal bronchocele. Usually the formation of an aneurysm is through percolation of the blood and air which is contained in the arteries, or by anastomosis of arteries, or by their rupture; the blood and air escape gradually and collect under the skin. Signs which accompany an aneurysm are: a small or large swelling, of uniform color, painless, extremely soft and elastic. It yields to the pressure of the fingers, so as to become almost imperceptible, and then again rapidly swells up.

Such, then, are the signs of the condition; no surgeons, however, will have anything to do with it when it occurs in the throat or the head; for as soon as an aneurysm is opened there takes place a most violent hemorrhage, very difficult to check, and at the same time a great quantity of vital pneuma (spirit) escapes; hence the individual undergoing operation runs the risk of dying on the physician's hands.

In the case, however, of aneurysm in the hollow of the elbow, we proceed thus: we first mark carefully the artery as it leads from above along the inside of the upper arm from the axilla to the elbow, and we make a simple incision along the inside of the arm, three or even four fingers' breadths below the axilla, where the artery mostly becomes palpable. Then gradually laying it bare, we gently strip it and free it from surrounding structures; then, drawing it up with a blunt hook, we apply two strong ligatures of twisted flax, at an interval of the breadth of a thick finger from one another. Tying these very firmly, we sever the artery midway between the ligatures; then, having filled the wound with manna and inserted a drain we apply bandages. Thereafter we incise the swelling in the hollow of the elbow, having no further fear of hemorrhage. After turning out the clots we search for and find the bleeding artery; this we draw out with hooks and ligature it like the former one; then again, filling the wound with manna, we have recourse to the suppurative treatment.

When we put ourselves in the hands of a physician, we don't want to detect freckles of gold dust. — Houston Chronicle 8/12/65

Medicine and Religion

Faith in Medicine—Two Forces, One Goal*

Throughout all America there is new recognition of the concept that man is a whole being: that he is physical, spiritual, emotional and social in his total health. It is also widely recognized that a weakness in any one of these four factors of his health can and does militate toward ill health in any one or two or all three of the other factors. All illness is not organic; the parents of the retarded child in some cases are more ill than the child. Moments of shock, fear, hysteria, and grief are moments of serious illness, which can affect the whole being of the patient.

The faith of the individual patient is a vital factor in total health, and he must be treated and cared for within the scope of that faith. There needs to be greater understanding between physicians and all faith groups as to the requirements of those faiths relative to patient care.

The physician recognizes that he treats but God heals. In the treatment and care of the patient, the faith of the patient has much to do with the healing process — the will to live or to die, and this cannot be purchased in a bottle at the drug store.

If man is to find total health, the abundance of life which has been promised to him by his creator, God, then it is essential and necessary that he develop to the fullest extent a perfect body, physically; a perfect mind, mentally; a perfect soul, spiritually; and a perfect life, socially. Whether our illness is physical or spiritual, we realize the need of the physician and the clergyman to associate themselves in concern for this total man.

"The church is primarily concerned with the patient's spiritual welfare and the physician with the patient's physical condition, but all of us are aware of the complexity of the individual and the importance of treating the whole patient," says Doctor Edward H. Rynearson of the Mayo Clinic. Among all the alliances in effect today, none, I believe, will prove more productive and beneficial to human welfare than the alliance of medicine and religion.

We hear the question: to what extreme does the doctor use extraordinary measures to maintain life, in view of the fact that it is his credo to do all in his power to sustain life? And what are "extraordinary measures"? That which was extraordinary ten years ago is ordinary today. Also, to what extent do we maintain the patient as a merely vegetating organism? We are not referring here to euthanasia or mercy killing, for medicine as a profession is opposed to both. The physician and the clergyman need to have dialogue in these areas; they need to discuss this carefully with understanding and compassion, so that the physician can be guided to a correct decision.

The confidence that the average family places in its clergyman and its physician requires that the two consult with each other whenever necessary. From their collective judgment will come the means for providing the most effective care and treatment of the patient as a whole man. This is the new concept.

These then, are the two forces — medicine and religion — operating with one objective, that you and I may receive the finest care and treatment in our illness, knowing full well that illness may be organic, may be spiritual, may be emotional or mental, may be social. This, then, is our goal — total care.

In Memoriam

No man who is fit to live need fear to die. — Fuller

WILLIAM R. LOVELACE, II, M.D.

Dr. William Randolph Lovelace II, 57, president of the Lovelace Foundation, Albuquerque, New Mexico and director of space medicine in the Manned Space Flight Division of the National Aeronautics and Space Administration, was killed, with Mrs. Lovelace, when an airplane which he had chartered crashed in Grizzly Gulch, near Aspen, Colorado, on December 12th. He was born in Springfield, Missouri, and received his degree of doctor of medicine from the Harvard Medical School.

Dr. Lovelace came to Rochester July 1, 1936, as a fellow in surgery of the Mayo Graduate School of Medicine, and was appointed a first assistant in surgery to Dr. Charles W. Mayo in 1939. He became a member of the staff of the Mayo Clinic in 1941. In 1940 with the late Doctors Walter Boothby and Arthur Bulbulian, he was given the Collier Trophy Award for his participation in the studies of the three men, which produced the Boothby-Lovelace-Bulbulian oxygen mask for the use of flyers at extremely high altitudes. In 1943 he made a parachute jump from a height of 40,200 feet to test oxygen equipment. In October to December, 1946, he was on leave of absence from the Mayo Clinic to practice surgery at the Lovelace Clinic in Albuquerque, New Mexico, and thereafter remained with the Lovelace Clinic.

Dr. Lovelace never relinquished his abiding interest in aviation medicine. In 1942 he was appointed director of research and consultant in surgery in the office of the Air Surgeon General, and in 1942 he was president of the Aero Medical Association. From then on, Dr. Lovelace held various offices in space associations and foundations. His awards and citations were many, and among these was the Outstanding Achievement Award from the University of Minnesota in recognition of noted professional attainment which he received in 1964 at the Mayo Centennial.

He was certified as a specialist in surgery by the American Board of Surgery in 1942; he was one of the founders, in 1953, of the sub-board of aviation medicine of the American Board of Preventive Medicine, and had been a fellow of the American College of Surgeons since 1942. He was a member of the board of directors of the Garrett Corporation, and of the Western Surgical Association, Pan-Pacific Surgical Association, the American Medical Association, the Aero Medical Association, the Association of Military Surgeons of the United States, the Institute of the Aeronautical Sciences, Inc., the African Research Foundation, the Space Educational Foundation and the Alumni Association of the Mayo Graduate School of Medicine.

He is survived by three daughters.

OLAF J. HAGEN, M.D.

A long-time leader in Minnesota's medical and educational circles, Dr. Olaf J. Hagen, 93, Moorhead physician, died December 3. He was born in Menomonie, Wisconsin, and received his degree in medicine from the University of Minnesota Medical School.

Among his honors was an outstanding achievement award from the University of Minnesota board of regents, to which he was named in 1931. He founded the Fargo Clinic, and succeeded the late Dr. Charles Mayo as president of the Minnesota Public Health Association.

He was a member of the American Medical Association and the Clay-Becker County Medical Society, and a 50 Club and life member of the Minnesota State Medical Association.

He is survived by a daughter and a son.

CARL B. DRAKE, M.D.

Dr. Carl B. Drake, 79, long-time officer of the Minnesota State Medical Association, died December 9, in his sleep. A life-long resident of St. Paul, he was a graduate of the University of Minnesota Medical School.

Continued

For thirty-four years, he served as school physician for the St. Paul Academy, was on the Ancker Hospital medical staff for forty years, and a member of the clinical faculty of the University of Minnesota.

Dr. Drake was a past secretary of the Minnesota State Medical Association. He was elected president-elect of the Minnesota State Medical Association but was prevented by illness from serving in this capacity. Dr. Drake was vice president and president of the Ramsey County Medical Society. He was editor of *Minnesota Medicine* from 1919 to 1953 and recipient of the Minnesota State Medical Association's distinguished service award. He was also a member of the American Medical Association and a 50 Club member of the Minnesota State Medical Association.

He is survived by his wife and three sons, one of whom is Dr. Emerson H. Drake of Portland, Maine.

CARL G. ARVIDSON, M.D.

Dr. Carl Gustav Arvidson, 74, Minneapolis physician, died December 12th. He received his medical degree from the University of Minnesota, and headed the Venereal Disease Clinic for Women at General Hospital from 1920 to 1925. He was a supervisor in venereal disease diagnosis at Sauk Centre Home School for Girls and at state institutions in St. Cloud, Shakopee and Stillwater.

Dr. Arvidson was on the staff at Swedish Hospital and belonged to the American Institute of Swedish Arts, Literature and Science. He was a member of the American Medical Association, Hennepin County Medical Society and a life member of the Minnesota State Medical Association.

He is survived by his wife and a daughter.

HARRY C. JENSEN, M.D.

Dr. Harry C. Jensen, 70, Minneapolis general practitioner, died January 2. He was born in Hutchinson, Minnesota, and obtained his medical degree at the University of Minnesota Medical School.

He was a staff member of the Deaconess Hospital, associate member of the Minnesota State Medical Association, member of the American Medical Association, member of the Hennepin County Medical Society and owner of the Edina Medical Center.

He is survived by his wife and a daughter. Dr. Verner M. Jensen of Morningside is his brother.

ROGER L. J. KENNEDY, M.D.

Dr. Roger L. J. Kennedy, 68, widely-known specialist in diseases of children and former head of the Section of Pediatrics of the Mayo Clinic, died January 14. He was born in St. Paul and received his degree of medicine from the University of Minnesota.

Dr. Kennedy was president of the Minnesota State Medical Association in 1952 and had served as president of the American Pediatrics Society. He was a former president and secretary and treasurer of the Northwestern Pediatric Society, a member of the editorial board of the *American Journal of Diseases of Children* from 1951 to 1961, a member of the council of the Minnesota State Medical Association from 1947 to 1951, had been a member of the House of Delegates of the American Medical Association, and was president of the American Academy of Pediatrics in 1953. In 1951 Pope Pius XII conferred upon him the order of Knight of St. Gregory the Great.

A fellow of the American Academy of Pediatrics, Dr. Kennedy was also a member of the Society for Pediatric Research, the Minnesota State Medical Association, the Southern Minnesota Medical Association, the Zumbro Valley Medical Society and the Alumni Association of the Mayo Graduate School of Medicine.

He is survived by his wife, a daughter and three sons. One of his sons, Dr. James Arthur, is engaged in medical research in the U. S. Air Force and another son, Michael, is a medical student at the University of Minnesota.

ARCHIBALD O. OLSON, M.D.

Dr. Archibald Olson, 65, prominent Duluth ophthalmologist, died January 6. Born in Mandan, North Dakota, Dr. Olson graduated from Rush Medical School in 1929.

He was a past president of the Minnesota Academy of Ophthalmology, a member of the American Academy of Ophthalmology, the St. Louis County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was a past chief-of-staff at St. Luke's Hospital and a member of the staff at St. Mary's and Miller Memorial Hospitals.

He is survived by his wife, a son and two daughters.

The surgeon should be learned, skilled, ingenious, and of good morals. Be bold in things that are sure, cautious in dangers; avoid evil cures and practices; be gracious to the sick, obliging to his colleagues, wise in his predictions. Be chaste, sober, pitiful, and merciful; not covetous nor extortionate of money; but let the recompense be moderate, according to the work, the means of the sick, the character of the issue or event, and its dignity. — Guy de Chauliac (circa 1295-1370)

Medical Economics

AMA Delegates Pass "Billing for Medical Fees" Resolution

Delegates attending the American Medical Association Clinical meeting in Philadelphia heard considerable discussion regarding the direct billing of patients as opposed to the acceptance of assignments for payment by a third party. In lieu of several resolutions, the delegates adopted a substitute resolution which included eight statements on fees charged by physicians for medical services. These are:

"1. The intimate relationship between physician and patient is served best without the interposition of any third-party carrier, whether in the area of diagnosis and treatment or the payment for these services.

"2. It is the patient's responsibility to deal with third-party carriers in the area of financial assistance provided that the physician is at all-times mindful of his obligations to the patient under Section 1 of the Principles of Medical Ethics.

"3. The physician-patient relationship is served best when there is an advance understanding regarding the payment of fees and the physician bills the patient directly for services rendered. However, the physician is ethically free to choose in each case the manner in which he is to be compensated, based upon the exercise of his independent judgment.

"4. The American Medical Association does not approve of any program which may directly or indirectly promote the charging of excessive fees or which interferes with the physician's right to charge fees commensurate with the services he renders.

"5. The American Medical Association opposes any program of dictation, interference, or coercion, whether direct or indirect, affecting the freedom of choice of the physician to determine for himself the extent and manner of participation or financial arrangement under which he shall provide medical care to patients under Public Law 89-97, or other third-party plans.

"6. It should be remembered that insurance does not create any new wealth. It merely assists in conservation. Insurance may conserve the ability of an insured person to fulfill his normal financial obligations. It does not enhance his ability to discharge added responsibilities if they are in the form of increased fees. To use insurance as an excuse to revise professional fees upward is but to contribute to the defeat of its purpose. If these indisputable and self-evident facts are not embraced by the entire membership of the profession, then it will have dealt irreparable harm to the whole movement. Also, any such failure might give impetus to whatever demand now exists for forcing rigid benefit schedules on the professional. (The

foregoing is from a report of the Council on Medical Service to the House of Delegates at the Clinical Meeting in 1954).

"7. The charging of an excessive fee is unethical and is contrary to Section 7 of the Principles of Medical Ethics. The physician's fee should be commensurate with the services rendered and the patient's ability to pay. (The foregoing is from a report of the Judicial Council which was approved by the House of Delegates at the Clinical Meeting in 1960).

"8. It is not contrary to conscience for the physician to consider the patient's ability to pay if he fixes his particular fee within reasonable limits. In matters relating to fees, the physician should try, to the best of his ability, to insure justice to the patient and himself and respect for his profession. (The foregoing is from an opinion of the Judicial Council in 1958)."

AMA Membership Dues Increase Voted

A $25-a-year increase in membership dues, effective Jan. 1, 1967, was endorsed by the AMA House of Delegates in Philadelphia when it was informed by the Board that additional income will be needed by then to avoid deficit spending.

The increase, to $70 a year for the AMA's 165,000 dues-paying members, will go before the House for final action at the 1966 Annual Convention, because AMA Bylaws state that annual dues may be prescribed by the House only for the ensuing calendar year.

Board Chairman Percy E. Hopkins, M.D. told the House that "during 1964 and 1965, the AMA will have incurred an operating deficit of more than 1 million dollars." The budget for 1966, he said, is now narrowly in balance.

The 1966 budget calls for spending some 27.6 million dollars, Doctor Hopkins reported, including almost 10½ million dollars on scientific programs, 5 million on health education and other medical service programs, more than 1 million to maintain physician records, and another million in the communication's program. Travel and meeting costs will exceed 2 million dollars.

"In a society," Doctor Hopkins said, "which has adopted inflation as a national policy and in which our system of medical care has become a pawn of politicians, it is not realistic to expect that we can limit tomorrow's programs to yesterday's income. Already demands are mounting from medical societies and physicians for a stronger and more effective AMA. These needs must be met, and they must be adequately financed."

Doctor Hopkins said that AMA's income in 1960 was just under 16 million dollars, while in 1966 it will exceed 27 million, an increase of 11 million. "This represents increases of 3.9 million dollars from membership dues, 4.3 million in advertising revenue, and 2.8 million from other sources.

"During this same period," he stated, "the challenges thrust upon the Association required even greater expenditures — from 15.7 million dollars in 1960 to a need for 27.6 in 1966."

In support of the dues increase, the House noted that AMA's dues-paying members provide less than 30 per cent of the Association's income.

Life is compatible with any disease, provided the bowels remain open; any kind of pain, provided the heart remains unaffected; any kind of uneasiness, provided the head is not attacked; all manner of evils, except it be a bad woman. — The Talmud

Coughing ahead...
Clear the Respiratory Tract with Robitussin.

Much more than just a slogan, "clear the tract" reflects the dependable antitussive-expectorant action of the three Robitussin formulations. All contain glyceryl guaiacolate, the time-tested expectorant that greatly enhances the output of lower respiratory tract fluid. Increased RTF volume exerts a demulcent effect on the tracheobronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise. Glyceryl guaiacolate is safe, non-narcotic, and almost universally accepted by patients of all ages.

too young
to be so tired...

revive interest...restore activity promptly with Alertonic®

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline†, 100 mg.; inositol†, 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.

the need for a tonic knows no age

Life *can* begin at forty—except when functional fatigue causes her to feel tired all the time; to start losing interest in friends and surroundings; to look and act older than her years. Alertonic—*a prescription tonic*—can help your patient become her normal self again. Alertonic helps relieve mild depression, revive interest and restore purposeful activity promptly...with a formula that is efficient *and* economical. Alertonic contains a mild central stimulant (pipradrol hydrochloride), 15% alcohol, essential vitamins and minerals. No hormones or MAO-inhibiting drugs are included. No iron. No iodine. One pleasant-tasting tablespoonful before each meal comprises the usual daily dose.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS-stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive-compulsive states.

Side Effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.

Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug.
Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

FREO, BY SAUNDERS SCHULTZ

FREE YOUR PATIENTS from

√ deficient neutralization

√ poor taste

√ burdensome cost

***with* DICARBOSIL® antacid**

- **effective neutralizing power**—Two tablets in vitro[1], provide nearly 2 hours' relief within effective pH range 3 to 5.5.
- **pleasant taste**—A fresh mint flavor patients continue to enjoy, because with Dicarbosil's unique* formulation, chalky aftertaste is no longer a problem.
- **exceptional economy**—Due to its high neutralization capacity combined with low cost (1¢ or less per tablet), Dicarbosil is within the reach of all patients.

ARCH LABORATORIES
A Division of Lewis-Howe Company
319 South 4th Street • St. Louis, Missouri 63102

DEPROL®

meprobamate 400 mg. +
benactyzine hydrochloride 1 mg.

Indications: 'Deprol' is useful in the management of depression, both acute (reactive) and chronic. It is particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination. It is also useful for management of depression and associated anxiety accompanying or related to organic illnesses.

Contraindications: Benactyzine hydrochloride is contraindicated in glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use.

Precautions: *Meprobamate*—Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Side effects associated with recommended doses of 'Deprol' have been infrequent and usually easily controlled. These have included drowsiness and occasional dizziness, headache, infrequent skin rash, dryness of mouth, gastrointestinal symptoms, paresthesias, rare instances of syncope, and one case each of severe nervousness, loss of power of concentration, and withdrawal reaction (status epilepticus) after sudden discontinuation of excessive dosage.

Benactyzine hydrochloride—Benactyzine hydrochloride, particularly in high dosage, may produce dizziness, thought-blocking, a sense of depersonalization, aggravation of anxiety or disturbance of sleep patterns, and a subjective feeling of muscle relaxation, as well as anticholinergic effects such as blurred vision, dryness of mouth, or failure of visual accommodation. Other reported side effects have included gastric distress, allergic response, ataxia, and euphoria.

Meprobamate—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Dosage: Usual starting dose, one tablet three or four times daily. May be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended even though higher doses have been used by some clinicians to control depression and in chronic psychotic patients.

Supplied: Light-pink, scored tablets, each containing meprobamate 400 mg. and benactyzine hydrochloride 1 mg.
Before prescribing, consult package circular.

FOR DEPRESSION

even when complicated by anxiety, tension, insomnia, agitation or rumination.

- Acts rapidly.
- Side effects at recommended dosage infrequent, usually easily controlled.

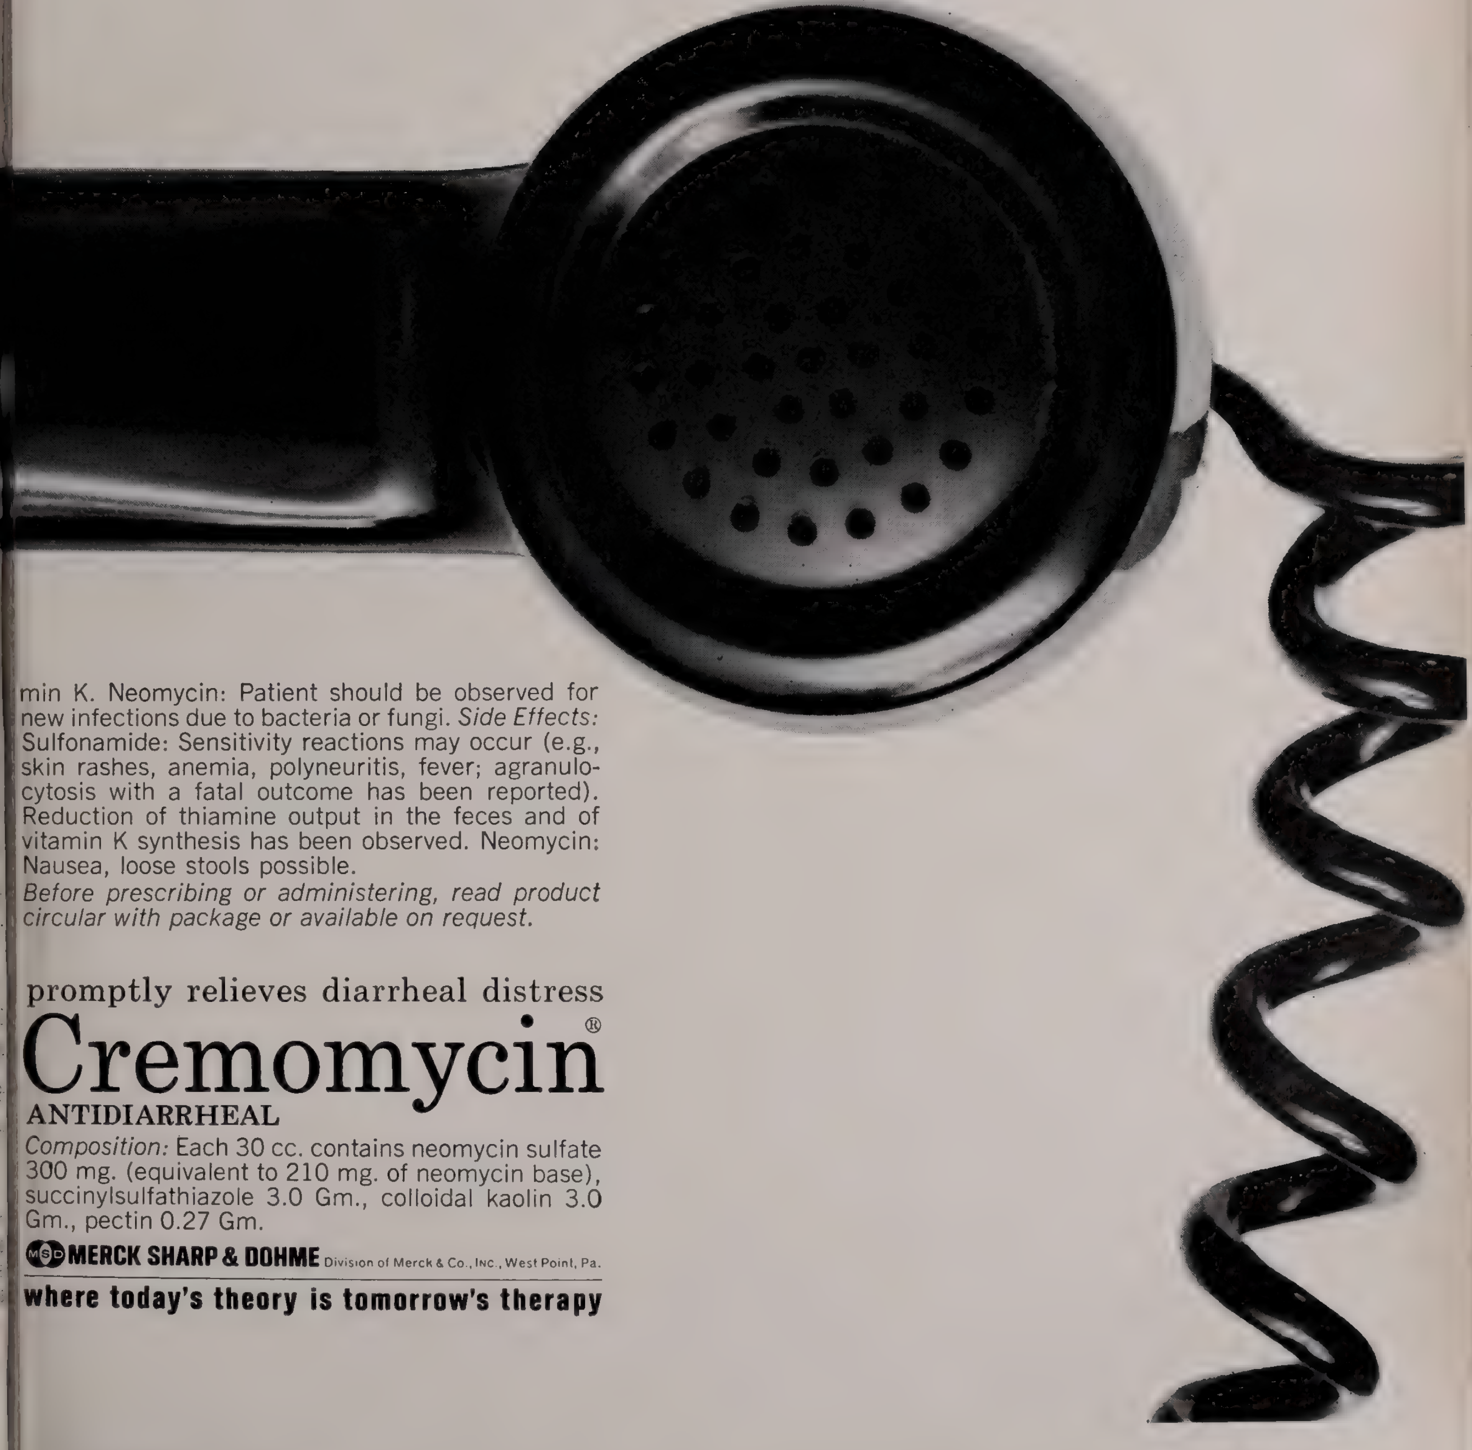
When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for
Cremomycin
can provide relief



min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.
Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress
Cremomycin®
ANTIDIARRHEAL

Composition: Each 30 cc. contains neomycin sulfate 300 mg. (equivalent to 210 mg. of neomycin base), succinylsulfathiazole 3.0 Gm., colloidal kaolin 3.0 Gm., pectin 0.27 Gm.

MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

where today's theory is tomorrow's therapy

Minnesota Medicine at a Glance

Tuberculosis and Human Bone Marrow — Schleicher Page 221

The knowledge that tubercles are found only in "marrow units" has made it possible to demonstrate the tubercle bacillus from the bone marrow in individuals suffering with otherwise indefinitely proven tuberculosis. This is possible when meticulous technique is carried out. Separation of the marrow units from the blood and free fat portion of the sample has been found to be important. Though the sternum is the preferred site from which to take the biopsy, the manubrium and the tibia can be used in younger children.

Arteriovenous Fistula — Naffah et al. Page 227

Arteriovenous fistula involving the renal vessels is relatively uncommon, but it may occur as a result of injury or it may be congenital. It is clinically manifest by fatigue, abdominal pain, a palpable mass, flank pain with shock, peripheral edema, fever, renal colic, headache, dyspnea, and hematuria. After an intravenous pyelogram shows some abnormality in the involved kidney, an aortogram can be made to confirm the diagnosis. This condition is amenable to surgical treatment, as has been indicated in the case report.

Sulfonamide-Resistant Neisseria Meningitidis — Walker & Strom Page 232

In some instances children with clinical meningitis can be found harboring sulfonamide-resistant Neisseria meningitidis which is resistant to the usual treatment with sulfonamide. In those instances it should be advantageous to realize that an effective means of determining sensitivity with a modified Wilson tube dilution technique is available, in order that these infants can be more advantageously treated with penicillin and sulfisoxazole.

Scintillation Camera for Brain Pathology — Loken et al. Page 237

The use of large amounts of radioactive material for the purpose of diagnostic scanning is sometimes contraindicated. By using the short-lived radioactive materials in which the half-life is about six hours, this hazard can be eliminated. Loken et al. have used a polaroid camera and the short-lived 99 m-TC radioactive material, and have found that the period of exposure is considerably diminished, thereby making the clinical application of this technique more valuable.

Vein Stripping in Pregnancy — Quattlebaum and Hodgson Page 245

Quattlebaum and Hodgson have made an extensive follow-up study of vein surgery in the pregnant woman and have observed that the final results are as favorable in the pregnant woman as in the nonpregnant patient. They recommend against the stripping of varicose veins during pregnancy except between the fourth and the seventh month of pregnancy, on the basis that to do so in the first trimester and during the last two months of pregnancy may disturb the pregnancy. The technique of vein-stripping is no different in the pregnant woman than it is in the non-pregnant.

Idiopathic Hypertrophic Subaortic Stenosis — Nydahl et al. Page 248

The authors review the pertinent physical, electrocardiographic, roentgenographic, and cardiac catheterization data of the lesion, idiopathic hypertrophic aortic stenosis. Three patients with this problem are described. Each patient had dyspnea, angina, left ventricular enlargement, and a systolic precordial murmur. Electrocardiographic and vectorcardiographic tracings substantiated the left ventricular changes as demonstrated by cinefluoroscopy and selective left ventriculogram. The ventriculogram also demonstrated the change in the septal muscle mass obstructing the left ventricular outflow tract.

Cardiac catheterization delineates the site of the obstructive left ventricular lesion as at the septum rather than at the aortic valve. The obstruction by the muscle mass may not be evident until the patient is exercised or receives an intravenous infusion of isoprotenol. Digitalis, Valsalva maneuvers, and the compensatory beat after an extrasystole will also aggravate the obstruction.

The hypertrophic left ventricle has low compliance and a low cardiac output. Despite normal coronary arteries these factors determine the symptomatology and eventual prognosis.

Intraspinal Arteriovenous Anomalies — Love et al. Page 255

The treatment of arteriovenous anomalies of the spinal cord has been disappointing, but recently Love et al. have had the experience of occluding the anomalous arteries after demonstrating them with retrograde aortograms. In the past there has been little hope for patients with this type of anomaly, and for the most part they have progressed to become paraplegic.

Treatment of Multiple Sclerosis — Grand Rounds Page 323

The treatment of multiple sclerosis has on the whole been unsatisfactory, but well controlled studies suggest that ACTH can provide some benefit in the treatment of the acute exacerbations of the disease. There are very few side effects, but the possibility of developing adrenal insufficiency during ACTH therapy must be watched for.

Forensic Psychiatry — Wilson Page 345

The McNaughton rules, established in 1843, were a list of answers given by the judiciary to the House of Lords on questions of criminal responsibility: "To establish a defense on the grounds of insanity it must be clearly proved that at the time of committing the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it that he did not know he was doing what was wrong."

The Durham rule formulated by Judge Bazalon: "An accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect." Under a different name, this rule was essentially established in 1887 in the state of New Hampshire by Judge Doe.

The difficulty with forensic psychiatry is that of adequately defining insanity.

A RELIABLE, PROVEN PRODUCT . . .
The BSP test, introduced in 1925, remains one of the most sensitive laboratory procedures available for determining hepatic function.

A STERILE, CONVENIENT PUT-UP . . .
Each BSP Disposable Unit contains: a sterile, glass, disposable syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of Bromsulphalein.

The BSP unit is designed for maximum patient protection. The precalibrated syringe makes weight calculations unnecessary and provides for proper dosage regardless of patient-weight.

ECONOMICALLY PACKAGED . . .
Prepared for economic unit dispensing, this completely disposable put-up affords a savings in time and labor—the most costly commodities.

Neo-Synephrine is a standard among topical vasoconstrictors. It is unsurpassed for reducing nasal turgescence in colds; and a most valuable aid in preventing and treating sinusitis.

Neo-Synephrine stops the boggy feeling of colds at once—works against factors that induce sinusitis. With Neo-Synephrine nose drops, spray or jelly, turbinates shrink on contact, obstructed ostia open and drainage is re-established.

In sinusitis, Neo-Synephrine helps to promote drainage and hasten recovery.* Used promptly, it helps clear the stagnant sinus and lessen the chances of chronicity.

Neo-Synephrine HCl is available in:
$^1/_8$% solution for infants
$^1/_4$% solution for children and adults
$^1/_4$% pediatric nasal spray for children
$^1/_2$% solution for adults
$^1/_2$% nasal spray for adults
$^1/_2$% jelly for children and adults
1% solution for adults (resistant cases)

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

PRIMARY PYODERMA

TYPICAL RESULTS

AFTER TREATMENT WITH
'NEOSPORIN' ANTIBIOTIC OINTMENT
AND SALINE COMPRESSES

with 'NEOSPORIN'® brand

Polymyxin B-Neomycin-Bacitracin

ANTIBIOTIC OINTMENT

Each gram contains:

'Aerosporin'® brand Polymyxin B Sulfate	5,000 Units
Zinc Bacitracin	400 Units
Neomycin Sulfate (equivalent to 3.5 mg. Neomycin Base)	5 mg.

Tubes of 1/2 oz. and 1 oz.

- clinically effective
- comprehensive bactericidal action against most Gram-negative and Gram-positive organisms, including Pseudomonas
- rarely sensitizes

For the eradication of infectious organisms in a wide range of dermatologic disorders: impetigo, ecthyma, pyodermas, sycosis vulgaris, paronychia, traumatic lesions, eczema, herpes and seborrheic dermatitis. Prophylactically, for protection against bacterial contamination in burns, skin grafts, incisions and other clean lesions, abrasions and minor cuts and wounds.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs.

Contraindication: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Complete literature available on request from Professional Services Dept. PML.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

President's Letter

In 1964 the House of Delegates of the Minnesota State Medical Association considered and approved a recommendation, developed after long discussion and hearings by the Committee on Medical Services, that component societies be advised of the rapidly developing need for utilization committee formation within each hospital staff. Further, the Committee was instructed from its experience to offer guidance and assistance to component societies and hospitals in their area, when requested. At that same time, several committees and councils of the American Medical Association were considering the same problem, and during the 1964 Clinical Convention adopted the recommendations of the American Medical Association Commission on the Cost of Medical Care. Included in these recommendations was the statement "the state and local medical societies should urge and assist the medical staffs of hospitals to form utilization committees." Basically, this was the same policy adopted by the Minnesota State Medical Association, and the same recommendation to hospital staffs.

Since the passage of Medicare legislation, the voluntary aspect of the development of utilization committees has changed and is now written into, and required by, Federal law.

As of this writing, many of the same objections, which our committee heard from individual physicians and spokesmen for organized physician groups, are still being heard. Now, however, these concerns and objections are not local in origin, but because of the compulsion in the law itself are originating in every area in which the law is to be applied.

Following the passage of the Medicare bill, prior American Medical Association intensive study and conclusions with reference to utilization committees crystalized in the inclusion of this topic in the agenda of Technical Advisory Committee #3 (Provider Participation). Three meetings of this committee with representatives of the Social Security Administration were held during November and December of 1965. At the first meeting a pattern of what was to follow developed. Strong objections by the American Medical Association group to implications in drafts prepared by the Social Security Administration Staff that state agencies might have the responsibility to review these utilization plans to determine effectiveness by review of select or sample cases, resulted in the statements that: (1) physicians cannot cooperate with such intervention by government agencies, (2) the role of fiscal intermediaries should be maximized and that of state agencies minimized, and (3) proposed duplication of fiscal intermediaries would work against compliance and cooperation. Further, the American Medical Association group requested that H.E.W. Secretary Gardner, the General Counsel, and the Health Insurance Benefits Advisory Council be advised that "the following strong recommendations are brought to your attention:

1. That utilization review must be recognized as a professional concern.

2. That intrusion into matters of professional committees by government agencies is without precedent and in conflict with the

Low host resistance? Consider the "extra" antibacterial activity of Ilosone®

Occasionally, therapeutic failure is due to the patient's inability to mobilize his defenses sufficiently to overcome infection. Typical of this is the debilitated patient, the premature infant, or the diabetic. It is in these patients that the high levels of antimicrobial activity of Ilosone are especially useful. Ilosone has demonstrated antibacterial levels two to four times those of erythromycin base or stearate. Furthermore, it attains them earlier and maintains them longer. Even the presence of food does not appear to affect the activity of Ilosone.

Contraindications: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

Side-Effects: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

Dosage: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

The Incompetent Cervix*

WILLIAM B. STROMME, M.D.
ROBERT M. WAGNER, M.D.
E. WILLIAM HAYWA, M.D.
Minneapolis, Minnesota

SELDOM IN our lifetime of practice are we witness to outstanding medical achievements. Probably the best known in our field of obstetrics and gynecology is the development by Papanicolaou of the cytologic study of the vaginal smear and of its subsequent clinical application in endocrinology and in cancer detection of the female generative tract. Of no less importance, we believe, to human salvage is the recognition of correctible causes of pregnancy wastage. As a specific example, in the past 20 years we have witnessed first, the recognition of the incompetent cervix and, subsequently, the development of successful methods of closure. In predisposed patients, the timely application of appropriate surgical measures can reverse an expected abortion rate of approximately 80 per cent to a salvage rate of approximately 80 per cent.

The occurrence of cervical incompetence, whether congenital or post-traumatic in origin, is a major complication of mid-pregnancy which may extend into the third trimester. Of an over-all pregnancy loss of 1.63 per cent in the second trimester, Stromme and Haywa[1] found the incompetent cervix to account for 16 per cent — second in known causes only to premature separation of the placenta. According to Taylor[2] the condition occurs about once in 500 pregnancies. However, once having occurred, the probability of recurrence in subsequent pregnancies is increased several-fold. The significance is not in the rarity of the phenomenon but in its predictable repetitiveness. For the individual so afflicted, this condition can be corrected with rewarding results.

The mechanism of cervical incompetence was first enunciated by Danforth[3] in 1947; he was the first to describe a congenital weakness or traumatic weakness of the fibromuscular junction at the site of the internal cervical os. It was his belief, since substantiated by others, that this weakness might result in a functional incompetence which would permit abortion in the second trimester. Palmer and Lacomme[4] in 1948, and independently Lash and Lash[5] in 1950, pioneered attempts at surgical correction of this weakness through reduction and closure of the presumed cervical scar. While Lash[6] has recently reported good results in over 95 cases, many of his postoperative patients failed to conceive. Believing that the defect might not be an anterior cervical scar, Shirodkar[7] developed the purse-string closure, first using chromic catgut; by 1955 — just 10 years ago — he reported his first series of 26 patients with only four failures. With similar yet independent thought, McDonald[8] introduced silk purse-string sutures for closure of the "traumatized" cervix; 33 of his series of 70 patients gave birth to surviving infants following his closure operation. Several modifications of the closure technique and different closure materials have been employed since these pioneer reports. Yet, with few exceptions, the basic cerclage* closure at the level of the internal os has prevailed as the choice of most practitioners.

---

*Presented at the 112th Annual Meeting of the Minnesota State Medical Association, May 17, 1965, in Minneapolis.

Widespread recognition of the importance of surgical correction of the incompetent cervix soon followed; and successful results[9-12] as published in the above and subsequent reports ranged from 66 to 100 per cent, varying more with selection of cases than with technique and closure material.

Indication for Use

This report is based on our experience with 51 patients, utilizing a modified Shirodkar operation. Selection of patients was based on significant past history, direct observation of developing cervical incompetence, or a combination of both. In a few instances, patients with unfavorable past histories had preconceptional investigation with Hegar dilators.

Functional Incompetence of Cervix

In agreement with several others, we believe that a functional incompetence exists when a Hegar dilator larger than a #6 size can be easily passed through the internal cervical os in the unanesthetized patient. When this was demonstrated, an elective operation was performed during the subsequent pregnancy.

History of Abortion Loss

Where there was history of late abortion losses in at least the last two pregnancies, the operation was done as a prophylactic procedure. The typical history was that of a "silent" labor, often preceded by a watery vaginal discharge and a sensation of pressure within the vagina. Except for occasional spotting, prior bleeding was notably absent. If examination in these patients found no other pathology to account for the losses, a modified Shirodkar operation was performed one or two weeks prior to the time of previous losses. Where the past history was not so clearly indicative of cervical weakness, and in all other patients, the operation was done as a therapeutic procedure. During the critical period patients were examined at weekly intervals and occasionally twice weekly, to ascertain developing cervical dilatation. At each visit, palpation and direct speculum examination was carried out; furthermore, patients were warned to report promptly any unusual watery vaginal discharge, spotting and/or "pressure" in the pelvis.

Dilated Internal Os

When a change in the cervix was noted, with the internal os dilated to but not beyond three or four cm., the patient was admitted to the hospital and the closure operation usually performed that same day. It is our[13] belief that dilatation of the cervix is slow and painless, and that opportunity is usually afforded to await these changes before performing the operation. Adherence to this policy, we believe, will justify the need for surgery when indicated and will obviate the need when not indicated.

Shirodkar Operation

A modified Shirodkar operation was performed 71 times in 51 patients. With but one exception, all were carried out during pregnancy. In six patients, in our earlier experience, it was necessary to repeat the operation during the pregnancy. In nine it was necessary to repeat the operation in subsequent pregnancies as a result of intentional or unintentional loss of cervical competence with vaginal delivery. Two patients have had the operation repeated in three successive pregnancies. Despite marked scarring in some instances the operation was performed in all patients with comparative ease. Blood loss averaged less than 100 ml. Transfusion was unnecessary.

While we have improved and on occasion modified our technique as we gained experience, the operation has remained fundamentally the same since first performed by us in 1957.

The Technique

The patient is placed in lithotomy position and vagina and cervix exposed. If the membranes are bulging, the patient is placed in deep Trendelenburg position to better facilitate the gentle replacement of the bag of waters above the level of the internal os. The cervix is grasped with sponge forceps and traction applied. Anteriorly, the mucosa is divided transversely at the level of the bladder reflection and the bladder dissected upward (Fig. 1-a). Using a curved Pean clamp, lateral submucosal channels are developed on both sides at this same level of the internal os. The cervix is then elevated, traction applied, and a similar transverse mucosal incision made posteriorly at this same level. Lateral submucosal channels are developed from below in the same manner as from above. Additional lateral traction is then made as the submucosal tunnel is completed using either a curved clamp or an aneurysm needle (Fig. 1-b).

---

*See Test Your Word Score Page 447.

Fascia Strip

If the latter is used, silk sutures are attached and carried through the channels on each side. The posterior free end of the sutures is attached to opposite ends of the fascia or tape, and this in turn is carried up through the submucosal tunnels (Fig. 1-c). If a curved clamp is employed, the free end of the fascia is grasped on each side and withdrawn through the tunnels, thereby developing the closure loop. Being satisfied that the fascial loop is placed well up at the level of the internal os, it is drawn taut and tied. Internal palpation confirms that a competent closure has been achieved (Fig. 1-d). The fascia is anchored to the cervix posteriorly with transfixing sutures of 000 black silk; the knot is similarly transfixed to the cervix anteriorly. Finally, the anterior and posterior mucosal defects are closed with continuous locked sutures of 000 chromic catgut. We have employed ox fascia in most cases (38) because of its advantage in permitting vaginal delivery without need for its division at the time of labor. In two instances, tight closure could not be achieved. In these and in other instances where ox fascia was

not available, synthetic polyester fiber strips* or reconstituted collagen film was used.

Pre and Postoperative Care

Preoperative and postoperative care was essentially that for minor pelvic surgery. We no longer employ antibiotics except where specifically indicated; however, long-acting progesterone (Delalutin) 250 mg. is usually given postoperatively to control uterine irritability. The anesthetic of choice has been intravenous pentothal supplemented by nitrous oxide and oxygen by mask. Provided there are no uterine contractions, the patient is ambulated on the following day. Careful examination of the cervix to determine its competence is carried out before the patient is discharged from the hospital, usually on the sixth or seventh day.

The Delivery

Our preference is for vaginal delivery and the majority of patients, including all in whom ox fascia was utilized, were successfully managed in this way. Where nonabsorbable material was employed, delivery was accomplished either by division of the tape and vaginal birth or by cesarean section, depending on extenuating and individual circumstances as well as the condition of the cervix.

Subsequent Pregnancies

Management in subsequent pregnancies was individualized, with close observation and expectant Shirodkar operation performed only when indicated by developing incompetence. Except where nonabsorbable tape had been used, with division and/or removal, repeat operation was seldom required despite previous vaginal delivery. As an example, our first patient with closure employing ox fascia was delivered by cesarean section at 38 weeks. She subsequently delivered vaginally at 37½ weeks, although repeat section was scheduled. Two years later she again delivered vaginally and now is once again pregnant with expectation of term vaginal delivery.

Results

This report is based on 51 patients with incompetent cervix treated by modified

---

Shirodkar operation on 71 occasions (Table 1). The average patient age was 31 years. Nearly one third (29 per cent) of the patients were 35 years or older. Past obstetric history was characterized by repeated losses, largely in the second trimester. Less than 20 per cent had living children. Forty-seven (77 per cent) gave no history of previous trauma and it was presumed that incompetence was based on congenital defect (Table 2). Previous trauma was noted in 14 patients; the several factors are listed. Significantly, two followed amputation of the cervix, one for chronic infection and the other following high amputation for squamous-cell carcinoma in situ.

Basis for the cerclage operation was about equally divided between prophylactic (52%) and therapeutic (48%) indications (Table 3). All were carried out in the second trimester, as early as 12½ weeks (previously amputated cervix) and as late as 28 weeks (therapeutic, previous failure). Average duration of pregnancy was 19 weeks with the mode at 20 weeks. For several years ox fascia was not available; during this time polyester fiber strips and other synthetic materials were used. Because of its predictable surety, which was not always obtained with ox fascia, we have lately preferred synthetic tapes for closure of the previously traumatized cervix.

Complications

The operation was virtually free of complications. There were no instances of associated hemorrhage and accordingly no need for blood replacement. Average blood loss was less than 100 ml. There was only one instance of amnionitis and no systemic postoperative infections. The membranes ruptured during the course of the operation on only one occasion, and this, unfortunately, occurred near the conclusion of the operation as the purse-string fascia was being tightened.

Eighty-four women became pregnant following the initial Shirodkar operation (Table 4). Of these, four are currently pregnant; four others lost subsequent pregnancies as early abortions, including one ectopic pregnancy. A total of 61 (74%) surviving infants have been delivered.

Unexplained	3	

*Four are currently pregnant; four had subsequent early abortions, including one ectopic.

**Five have subsequently carried pregnancies to term following repeated operation; a sixth is currently six months pregnant.

***Premature rupture of membranes, operation closure secure; viable infants, death from (1) Hyaline Membrane Disease (2) Mongolism.

Failures

In terms of failure of survival, the gross failure rate was 18 per cent (15). Five of these women subsequently conceived and, after repeat Shirodkar operations, successfully carried to term; a sixth woman is now six months pregnant. When corrected on the basis of maintaining a satisfactory competence of the cervix following the operation, there were only 10 failures. Premature rupture of membranes occurred in four instances following over-activity; in these, it was necessary to divide the synthetic fiber band to permit vaginal delivery. Included was a viable infant of 1640 gm. who died of hyaline membrane disease; a fifth infant was delivered at term but died on the fifth day from mongolism. The attributable causes for these failures are the following: premature separation of the placenta (3), faulty technique (3), premature rupture of membranes (over-activity) (4), submucous myoma (1) — the operation was probably not indicated in this case despite two previous second trimester losses, — and unexplained (3).

Method of Delivery

Vaginal delivery of surviving infants (and all nonviable births), was successfully performed in 44 patients (72%) (Table 5). In 11 of these it was necessary to divide the nonabsorbable tape early in labor. In only one patient was there hemorrhage (1500 ml.) related to laceration and bleeding from the cervix following tearing and slippage of the polyester fiber ring. Seventeen patients were delivered by cesarean section (16 as elective operation, one following a period of trial labor).

Post-Partum Findings

Post-partum studies were performed on 19 patients to determine whether or not cervical competence had been destroyed by vaginal delivery. All had been closed by ox fascia. The same Hegar dilator test was employed as earlier described. All tests were made from seven to 77 weeks post partum, with average at 12 weeks. In 14 patients the cervical competence was maintained; however, in five a #7 Hegar could be passed with ease, indicating loss of competence. Two of these subsequently became pregnant, and competence of the cervix was again restored with the use of polyester fiber tape.

Discussion

In the majority of cases previous cervical trauma does not play a role in the etiology of the incompetent cervix. We have reserved the operation for those women with developing cervical dilatation. Admittedly, we have on one or two occasions missed the opportune time for correcting the weakness, and in one instance, with the cervix four cm. dilated, membranes inadvertently ruptured during the course of the operation. On the other hand, in several cases with unfavorable histories, we have been surprised in our weekly examinations to follow these patients through to term without need for closure. Experience has taught us that cerclage at a higher level, is preferable; it is not necessary to transfix the cardinal and uterosacral ligaments, as suggested by Mann.[14] Except for the one patient with high amputation of the cervix where the vaginal approach failed, there would seem to be no justification for the abdominal approach, as recommended by Benson and Durfee.[15]

Where the cervix is of sufficient length and is unscarred, we prefer to use ox fascia as the closure material, as it handles well and can be drawn to a tight closure of the internal os. In time it is replaced by fibrous connective tissue which maintains a competence to term and yet allows vaginal delivery.

Where the cervix has been deeply scarred with previous lacerations, polyester fiber is preferable to tape, since under these circumstances, it may be possible to achieve a tighter, more lasting closure.

Our preference is for vaginal delivery. Thus, except for patients with marked cervical scarring or for those with additional obstetric indications, cesarean delivery would hardly seem warranted, except in the interests of maintaining a competent cervix for future pregnancies.

Conclusions

Incompetent cervix is a well-recognized cause of pregnancy wastage. It may be of congenital or traumatic origin.

Corrective surgery may be performed on a prophylactic or therapeutic basis; in the latter circumstances, frequent examinations will permit timely intervention.

The modified Shirodkar operation is easily performed with virtually no risk to patient or fetus; and a good cerclage technique is probably more important than the choice of closure material.

Vaginal delivery is practical in most cases. Division of the tape will be necessary only where nonabsorbable material is employed. Cesarean delivery may be preferred when the cervix is badly scarred and for other obstetric indications.

Old Age

Thor, who loved to extoll his physical powers, had been outdone by King Utgard-Loki, who had wagered with Thor that he could not lift from the ground a mere cat which was found to be Midgard, the formidable world serpent.*

After this defeat Thor was anxious to redeem himself, and he offered to wrestle with any of the giants that might be assigned to him. The king replied that it was beneath the dignity of any of his men to compete with the likes of Thor; instead, he called in an aged female, Elli (Annodomini), to wrestle with his guest. Chagrined, but assuming it would require only a smidgen of strength to seize and floor her instantaneously, Thor laid on but couldn't budge the old lady. Instead, after calmly standing her ground for a while, she abruptly forced him down onto one knee — whereupon Utgard-Loki called off the match.

So, twice had the doughty God Thor been ignominously vanquished: once by a mere cat and once by an old woman!

However, things are not always what they seem.

As for Elli, she was Old Age — and what man had ever bested her!

REVASCULARIZATION PROCEDURES in the lower limb for arteriosclerotic occlusion of the superficial femoral artery must be individualized because of variations in the extent of disease found to be present on surgical exploration. Whether the occlusion is corrected by endarterectomy or bypassed with a plastic prosthesis or autogenous vein depends to a degree on the personal preference of the operating surgeon.[1-3] Endarterectomy has proved to be successful, but if it is to be performed over any considerable length of vessel, bits of roughened intima may be left behind with a propensity towards reocclusion. The ready availability of the plastic prosthetics has given great impetus to the growth of peripheral vascular surgery, but long term follow-up studies[4,5] have revealed a rather high rate of late occlusion. The problems of excessive foreign-body reaction and infection are real and mitigate against the use of prosthetics below the inguinal ligament.

During recent years there has been a general trend towards the use of the vein autograft sewn between the common femoral and popliteal arteries.[6] This procedure, although time-consuming, avoids the necessity of using a foreign body and involves a minimum of intimal trauma. However, in order to preserve viability and usefulness of the limb, there are certain instances wherein a variation of this procedure has merit: if an infection has occurred in a previously performed femoral popliteal shunt, it may be desirable to avoid the infected field by constructing another shunt in a clean field prior to removal of the contaminated graft. A technique for constructing a profunda femoris-popliteal shunt through a posterior approach has been previously described.[7]

A second circumstance in which an alternative procedure may be desirable is in the patient who has had a prosthetic aortofemoral graft successfully inserted, and who subsequently develops a superficial artery occlusion requiring a lower limb revascularization procedure. Exposure of the lower end of the previously well incorporated graft should be avoided as this increases the risk of infection and anastomotic breakdown.

A suitable alternative procedure has proven successful wherein the saphenous vein was removed from the thigh and used as a profunda femoris-popliteal shunt around the occluded superficial femoral artery. Exposure was gained through the same incision required to remove the vein but without dissecting out the previously incorporated graft, the common femoral artery, or the occluded superficial femoral artery.

---

Popliteal Shunt

Medical Approach

Case History

A 59-year-old male had a knitted Teflon iliofemoral bypass graft inserted on June 19, 1963, for an occluded left external iliac artery. He had complained of intermittent claudication in the left calf prior to surgery but was asymptomatic afterward.

Fig. 1 — (a-left) Preoperative arteriogram demonstrating occlusion of the superficial femoral artery (b-middle) Diagram depicting the operative procedure (c-right) Arteriogram three days following surgery.

His relief lasted for over a year, but he noted the gradual return of similar symptoms and was admitted on March 20, 1965, for evaluation. At this time the Teflon shunt was working well as determined by a strong femoral pulsation; however, there was no palpable pulsating vessel below this point. A femoral arteriogram (Figure 1-a) demonstrated an occluded superficial femoral artery, an open popliteal artery, and a large profunda femoris artery.

The Surgical Procedure

At surgery on March 23, 1965, an incision was made over the course of the saphenous vein in the left thigh and the vein subsequently removed and placed in a solution of saline with 1% procaine and heparin added. The procedure was then continued by retracting the sartorius muscle superiorly and laterally and dissecting downward on the anterior surface of the adductor longus muscle until the deep femoral vessels were reached just before they dipped posteriorly behind the adductor muscles (Figure 1-b). A very adequate exposure of the profunda femoris artery was obtained after dividing several small branches of the deep femoral vein. The popliteal artery was dissected free, carefully preserving its collateral branches, and the saphenous vein reversed and sewn end to side to the popliteal artery and end to side to the profunda femoris artery. A strong pulsation was achieved when the vascular clamps were released. After surgery the dorsalis pedal pulsation was present, and a repeat arteriogram (Figure 1-c) demonstrated a functioning shunt.

Four days after surgery the patient suffered a myocardial infarction and had several mild ischemic cerebral episodes which may indicate carotid artery disease. When last seen three months after surgery, the shunt was open and working well, as determined by a lack of claudication on walking, a palpable dorsalis pedal pulse, and a warm foot.

Discussion

The incision made is the same as that for a femoral popliteal shunt with the exception of the superior portion of the wound where the dissection is deep and medial to the superficial femoral and common femoral arteries. The profunda femoris artery is exposed approximately two to three inches below its origin, and the anastomosis at this point can be made without difficulty. The graft is placed in a gentle arc over the sartorius muscle or tunneled under the muscle if the angle appears too sharp.

There are two advantages to this approach. First, the profunda femoris artery is frequently soft and pliable, whereas the common femoral and superficial femoral arteries are commonly arteriosclerotic; in addition, occlusion of the superficial femoral artery is often accompanied by an enlargement of the profunda femoris artery, making it more suitable as a source for a shunt. Second, the previously well incorporated graft need not be exposed. A theoretical disadvantage is that the dissection which is required about the deep veins of the thigh could predispose to subsequent venous thrombosis.

Summary

There is reason to avoid exposure of a previously well incorporated aorto-femoral or ilio-femoral prosthetic shunt when a second and lower limb revascularization procedure is required. A medial approach to the profunda femoris artery was utilized in order that the previous graft could be avoided and the saphenous vein was removed through the same incision and used as a profunda femoris-popliteal shunt.

Cardioversion of Ventricular Tachycardia Following Myocardial Infarction[*]

HANS ABERG, M.D.[**]
DONALD B. SWENSON, M.D.[†]
St. Paul, Minnesota

VENTRICULAR TACHYCARDIA is a rapid, fairly regular rhythm caused by stimuli originating from one or more irritable foci in one of the ventricles. The rate is commonly between 150 and 200. Ventricular tachycardia is believed to occur in two to four per cent of myocardial infarctions and is a serious complication.[1] It results in further impairment of myocardial blood flow and in decreased cardiac output with resultant fall in blood pressure. These factors potentiate each other in a vicious manner. Ventricular tachycardia may proceed without warning to ventricular fibrillation or asystole and can be either the cause of an infarction or a complication thereof. Early recognition and treatment is essential.

Etiology

Although paroxysmal ventricular tachycardia most commonly occurs in severely diseased hearts we now know with the help of the long term electrocardiographic monitor that this arrhythmia is more common in apparently healthy persons than earlier supposed. Semler has reported the case of a 16-year-old boy who had four attacks of ventricular tachycardia recorded on the electrocardiographic monitor during an examination at school.[2] However, extensive cardiac evaluation including several exercise tests failed to reveal any abnormality. The patient has been symptom-free since administration of quinidine.

The most common conditions associated with ventricular tachycardia are:

1. Coronary heart disease with or without myocardial infarction, and hypertensive heart disease.

2. Heart surgery and cardiac catheterization.

3. A miscellaneous group, including rheumatic fever, myocarditis, myocardosis[‡] and

Wolff-Parkinson-White syndrome (extremely rare).

4. Electrolyte disturbances such as hyperpotassemia and also digitalis, pronestyl (procaine amide) and quinidine intoxications.

5. Unknown.[3,4]

The frequency of the different causes for ventricular tachycardia has been reported in a review of 107 cases by Armbrust and Levine.[5] They found this arrhythmia associated with coronary heart disease in 74%, with rheumatic heart disease in 8.4%, and with no known heart disease in 12%. The remaining group consists of miscellaneous types.

Treatment

Massage Carotid Sinus

Vagal stimulation with the use of carotid sinus massage should be attempted in all instances of supposed ventricular tachycardia. Conversion of the arrhythmia or transient slowing of the rate by this mechanism strongly suggests a supraventricular origin. Absence of effect by carotid sinus massage suggests but does not prove the presence of a ventricular arrhythmia.

Drugs

Pronestyl or quinidine is the drug of choice in this arrhythmia,[6,7] the former being preferable because of its greater safety during intravenous administration. The recommended dosage is 2000 mg. of pronestyl in 100 cc. 5% dextrose in water with an infusion rate of 100 mg. every two to five minutes. A second bottle containing 100 mg. aramine (metaraminol) in 500 cc. 5% dextrose in water should be connected and ready for use if a significant drop in blood pressure should occur. During the infusion of pronestyl continuous electrocardiographic monitoring should be obtained, or at least a short run every minute. If widening of the QRS complexes develops, suggesting toxicity to the pronestyl, the rate must be slowed or the infusion stopped.

Suggested oral maintenance dosages are 500 to 750 mg. of pronestyl every four hours, or 200 to 400 mg. of quinidine every four hours. These initial dosages can be gradually tapered.

Other drugs have been used in the treatment of ventricular tachycardia, such as xylocaine (diethylaminoacet-2,6-xylidide hydrochloride) and dilantin (diphenylhydantoine).[8,9] Dilantin in particular seems to be promising in this field as well as for certain supraventricular tachycardias. In personal communication Dr. Richard Langendorf has described one case of ventricular tachycardia that initially did not respond to pronestyl but after an unsuccessful electric countershock was easily converted with pronestyl.

Disadvantages of Drug Therapy

Some of the disadvantages of drug therapy are that:

1. Ventricular tachycardia may not respond favorably to these drugs in any dosage and valuable time may be lost in arriving at this conclusion.

2. The addition of intravenous fluid can impose an undesirable burden on a heart in borderline failure. This is especially true when large dosages of medication are required.

3. Severe toxic reactions to the medications may occur. Along with the desired effect of suppressing ectopic pacemakers, depression of normal cardiac contractility can occur, resulting in fall in blood pressure. This hypotension enhances the development of ventricular fibrillation. Asystole is seen more rarely.

4. It may be difficult if not impossible on the electrocardiogram to establish the origin of the ectopic pacemaker. If supraventricular tachycardia with widened QRS complexes is erroneously diagnosed as ventricular tachycardia, pronestyl will likely do nothing. If ventricular tachycardia is erroneously diagnosed as supraventricular tachycardia with widened QRS complexes, the administration of intravenous digitalis is hazardous.

There have been many successful reports on the use of the alternating current defibrillator in terminating ventricular tachycardia, primarily by Zoll and his associates.[10-13] The use of synchronized capacitor discharge as a method to terminate this arrhythmia was first described in 1962 by Lown.[14] Our case reports are with the use of the Lown Direct Current Cardioverter.

Cardioversion

The application of brief high voltage direct current across the intact chest so timed as to avoid ventricular fibrillation depolarizes the heart muscle and ectopic foci, allowing the normal sinus pacemaker to take over. This assumes: a) The factors initiating the arrhythmia are different from the factors sustaining it, and b) The normal sinus pacemaker is intact and able to take over: i.e., you do not have the "sick sinus syndrome."

Advantages

Cardioversion by this method is simple, precise and immediate; it does not depress cardiac rhythmicity or contractility; it is effective in all types of arrhythmias;[15-17] and there are no documented reports of myocardial damage either experimentally in dogs or in human beings. This includes cases of myocardial infarction. The danger of embolization is probably similar to that after conversion of arrhythmias with drugs.

Disadvantages of the Cardioverter

Cardioversion is not invariably effective. A light general anesthetic is usually needed; but when as little as 50 Watt-seconds is used, it is not always necessary. It would seem prudent not to attempt the procedure except in the presence of an anesthesiologist or nurse anesthetist. The cardioverter stops but does not prevent recurrence of the arrhythmia, and precise familiarity with the equipment is essential. Lack of respect for high voltage electricity may lead to cardioversion of yourself or your associates without the benefit of programing the shock to peak of your QRS complex.

The exceptional safety of the Lown D.C. Cardioverter is due to the synchronization of the counter shock with the least vulnerable phase of the cardiac cycle, namely at the height of the QRS complex. Shocks administered on the upsweep of the T-wave are prone to produce ventricular fibrillation, and those at the termination of the QRS complex may result in atrial fibrillation.

Indications

The indications for drug therapy versus cardioversion are still somewhat controversial.[18,19] Initially, Lown used only D.C. Cardioversion in cases refractory to drugs. At present there seems to be an agreement to use cardioversion in those patients who do not respond to drugs within a short time and in cases in which the course is complicated by shock or pulmonary edema.

Diagnostic Features of Ventricular Paroxysmal Tachycardia[20]

The diagnosis of ventricular paroxysmal tachycardia is *suggested* when there is a rapid succession of three or more ventricular beats of bizarre contour, premature in onset and followed by a pause, with QRS complexes prolonged to more than 0.12 seconds and the ST-T opposite in direction to and often continuing directly from and into the QRS. The ventricular rhythm may be regular or irregular, and sometimes upright P-waves can be identified (in Leads II, III and AVF) at an independent and slower rate, or retrograde P-waves definitely follow the rapid ventricular complexes.

The diagnosis is *established* when there are occasional conducted beats with QRS less prolonged than in the beats of the tachycardia (ventricular *captures* by supraventricular impulses), or when there are ventricular fusion beats between ectopic and sinus impulses (except in the pre-excitation syndrome, WPW).

Normally, the cardiac impulse originates in the sinus node and spreads radially through the atrial muscle. In this spread, the A-V node is activated and transmits the impulses to the ventricles along the common bundle, its branches, and the Purkinje network.

While ventricular tachycardia can be suspected on the basis of a wide, bizarre contour to the QRS complexes, this is not absolute proof, since a nodal tachycardia can be associated with aberrant ventricular conduction or a pre-existent bundle branch block and thus cause prolongation of the QRS.

The two above mentioned electrocardiogram criteria for ventricular tachycardia are unfortunately rare. We were unable to demonstrate either of these beats: ventricular capture or ventricular fusion, in our cases.

Case Reports

Case #1

A 65-year-old farmer who developed anterior chest pain on May 1, 1964, was admitted to another hospital. His electrocardiogram was consistent with anterior myocardial infarction. The transaminase (S-GOT) was 150 units on the third hospital day. On the 18th hospital day he developed a heart rate of 162 with electrocardiographic evidence of probable ventricular tachycardia. This persisted for 17 days despite large dosages of pronestyl orally and intravenously. He was then transferred to the Bethesda Hospital. His blood pressure was 95 systolic, his heart rate was 150, and there was evidence of left ventricular failure. There was no response to carotid sinus massage. The electrocardiogram was believed consistent with ventricular tachycardia. Under pentothal anesthesia he received one shock of 100 Watt-seconds with conversion to atrial tachycardia with a 2:1 block. He quickly reverted spontaneously to sinus rhythm. Figure 1 shows the ventricular tachycardia and the re-established sinus rhythm. After the counter shock his blood pressure rose immediately to 120/75 and his general condition improved progressively. Two weeks after cardioversion he again developed atrial tachycardia with a 2:1 block with a ventricular rate of 132. He was given oral digitalis with reversion to sinus rhythm. He has remained well.

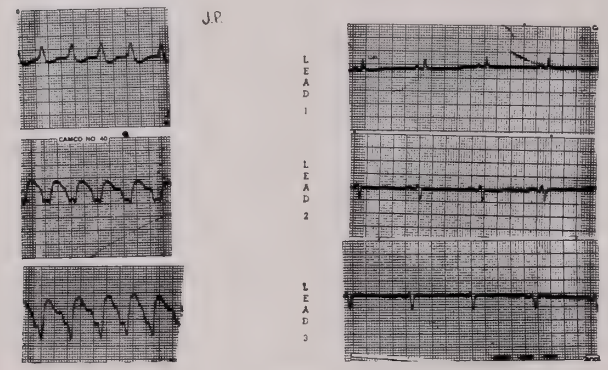

Figure 1

Case #2

A 65-year-old farmer was admitted to the Bethesda Hospital on July 2, 1964, with a history of severe chest pain several weeks earlier. He entered because of weakness of one week's duration. Blood pressure was 90 systolic. Chest X ray showed cardiomegaly and pulmonary congestion. His electrocardiogram showed a heart rate of 140 with widened QRS complexes which varied in configuration. No P-waves could be seen with certainty. Carotid sinus massage had no effect. Both pronestyl and quinidine were utilized without effect on the tachycardia, as seen in Figure 2. On the 12th hospital day a shock of 100 Watt-seconds was administered with establishment of sinus rhythm and immediate clinical improvement. The electrocardiogram was believed consistent with subacute posterior myocardial infarction. He was discharged in good condition 10 days after the cardioversion on oral pronestyl. He died suddenly two months later on the dance floor.

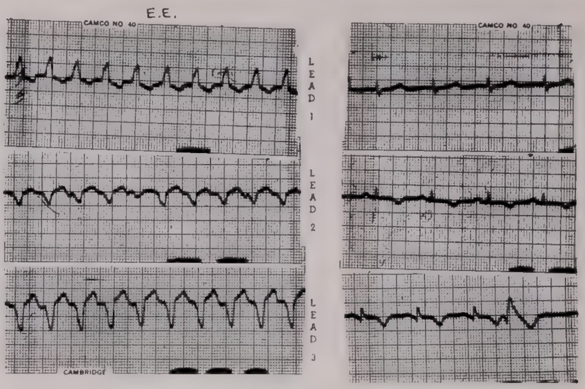

Figure 2

A 52-year-old printer, admitted to the Bethesda Hospital on September 9, 1964, had a history of pain in the chest and left shoulder five days prior to admission while mowing his lawn. Two days later he noted rapid beating of his heart. On admission his heart rate was 182 with an electrocardiogram consistent with ventricular tachycardia (Fig. 3). His blood pressure was 95 systolic. There were fine moist rales at the lung bases and tenderness over the liver. There was no response to carotid sinus massage. Pronestyl was administered intravenously without effect. Under pentothal anesthesia cardioversion was performed using a single shock of 100 Watt-seconds with conversion to sinus rhythm. His blood pressure rose quickly to 120/70 and he showed immediate clinical improvement. Subsequent cardiograms in the hospital were consistent with posterolateral infarction. He has remained well.

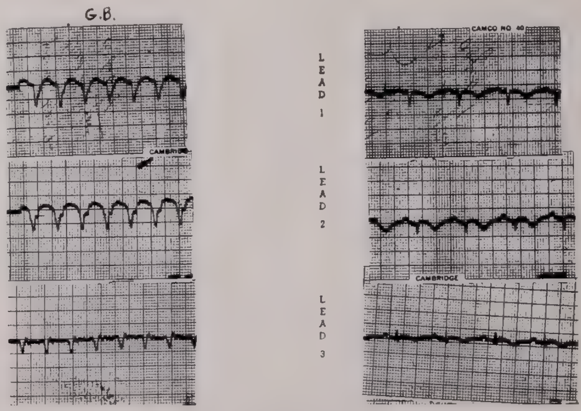

Figure 3

Case #4

An 80-year-old widow was admitted on April 12, 1965, with a history of vague chest distress. She was apprehensive and covered with cool perspiration. Her blood pressure was 100/70. Her heart rate was 204 and the electrocardiogram was interpreted as showing probable ventricular tachycardia. Repeated carotid sinus massage was ineffectual. Without a trial of pronestyl and without anesthetic, cardioversion was administered using 50-Watt-seconds. Sinus rhythm was then obtained. Her electrocardiogram before and after the counter shock are seen in Figure 4. Despite oral pronestyl, 250 mg. every four hours, she developed a recurrent tachycardia at a rate of 180 and was then noted to have a left hemiplegia. This arrythmia reverted to a slow sinus rhythm after pronestyl given intravenously. Six days later she developed atrial fibrillation with a ventricular rate of 190 and was given intravenous cedilanid with reversion to sinus rhythm. On the 11th hospital day she expired. Post-mortem examination showed evidence of recent as well as old myocardial infarctions. The transaminase (S-GOT) was 150 on the third hospital day.

Summary

Four patients with recent myocardial infarctions developed paroxysmal tachycardias believed to be of ventricular origin and were successfully treated with the Lown D.C.-Cardioverter. Three of the four had been refractory to other medical treatment. In seriously ill patients or in cases in which the electrocardiographic interpretation of a tachycardia is uncertain, the cardioverter fulfills a unique and useful role.

On Extracting Bones

It will often happen in eating that fish-bones or other objects may be swallowed and get caught in some part of the throat. If they can be seen they should be removed with the forceps designed for that purpose. Where they are deeper, some recommend that the patient should swallow large mouthfuls of bread or other such food. Others recommend that a clean soft sponge of small circumference to which a string is attached be swallowed, and then drawn out by means of the string. This should be repeated until the bone or other object gets caught in the sponge and is drawn out. If the patient is seen immediately after eating, and the swallowed object is not visible, vomiting should be brought on by means of a finger in the throat or irritation with a feather, and then not infrequently the swallowed object will be brought up with the vomit. — Paul of Aegina (7th century)

You can't leave footprints on the sands of time by sitting down. — Dr. Karl Berns

The Doctor and Literature – Part III*

Oscar Wilde

Oscar Wilde, now acclaimed by discerning critics of all nations as the author of the finest farce in the English language, *The Importance of Being Earnest,* and of the poignant *Ballad of Reading Gaol,* was accused by the Marquis of Queensberry of having an unnatural relationship with Lord Alfred Douglas.

In a farcical trial before the prejudiced Justice Wills, Wilde was found guilty of homosexuality and sentenced to two years at hard labor, first at Wordsworth Prison and later at Reading Gaol.

Upon his release, Wilde was ostracised by the English philistines and after a few miserable years died in exile in Paris of cerebral meningitis, his creative genius destroyed in shamelessly borrowing money from his friends and cadging drinks from American tourists. Wilde's genius was purified and matured by his terrible suffering in prison which he summarizes in the lines:

> "We did not dare to breathe a prayer
> Or give our anguish scope
> Something was dead in each of us
> And what was dead was hope."

Henry Fielding

Henry Fielding, in his novel *Amelia,* gives a grimly realistic picture of medicine as practiced in the Eighteenth Century.

After the Apothecary Mr. Arsenic had failed to cure Amelia's child, another doctor was called in for consultation.

"The first thing the new doctor did was to cause all powders and potions to disappear at his command. For he said there was a much easier and nearer way to convey such stuff to the vault than by sending it first through the human body. He then ordered the child to be blooded, give it a clyster (an Eighteenth Century term for an enema) and some cooling physic and within three days cured the little patient of her distemper."

Sinclair Lewis

The ultimate evaluation of a novel is how it stands the test of time. In the forty years since it was published in 1925, *Arrowsmith,* by Sinclair Lewis still remains by critical acclaim the finest American novel about a doctor.

The tragedy of Sinclair Lewis' life was too much too soon. Born in Sauk Center, Minnesota, in 1885, the son of a country doctor, Lewis went to Yale in 1908. He was unpopular with his classmates, because he was a critical nonconformist. He travelled widely and became a free-lance writer who sold several popular short stories to the *Saturday Evening Post.* In 1914 he married Grace Livingstone Hegger, by whom he had a son, Wells, who was killed in the war in 1944.

Main Street, published in 1920, made Sinclair Lewis the most widely read and successful novelist of the Nineteen Twenties.

The novel was a scathing satire on Carol Kennicott's abortive efforts to jar the smug, self righteous town folk of Gopher Prairie, Minnesota, out of their provincialism and intolerance. After many heart-breaking failures Carol accepts her fate, but is determined her children will have a better life by escaping from Gopher Prairie.

Acute Cholecystitis

- Due to
- Coagulase
- Positive
- Staphylococci

CLAUDE V. DE SHAZO, M.D.*
ROBERT P. BELIN, M.D.*
JUDSON F. LLOYD, M.D.*
ARNOLD I. WALDER, M.D.**
Minneapolis, Minnesota

ACUTE CHOLECYSTITIS, most commonly initiated by impaction of a stone in the ampulla of the gallbladder,[1] is often accompanied by infection. Primary infection of the gallbladder is considered the etiology in the five to ten per cent[1] of patients with cholecystitis who have acalculous gallbladders. An occurrence of acute calculous cholecystitis due to coagulase positive *Staphylococcus aureus* is the basis for this report. We have been unable to find any previous report of such a case.

Case Report

A 26-year-old female was admitted to the University of Minnesota Hospitals in April, 1965, after four days of fever and severe right upper quadrant pain radiating to the right scapula. During the preceeding five years she had had several similar episodes, some with jaundice. She had never been hospitalized, had no known contact with hospital personnel, had never been treated with antibiotics.

Physical examination revealed a well-developed, well-nourished woman acutely ill with nausea, abdominal pain, and a temperature of 100°F. (rectal). An exquisitely tender mass was palpated in the right upper quadrant of the abdomen. Muscle guarding but no rebound tenderness was present. The hemoglobin was 15.8 gm. per 100 ml. and the white blood count 17,700 with 85 per cent neutrophils. The total serum bilirubin was 0.9 mgm. per 100 ml.

The patient was treated with nasogastric suction, intravenous fluids and tetracycline. Six hours after admission her temperature was 102.8°F. (rectal) and her white blood count 15,500. Twelve hours after admission her temperature was 103.6°F. (rectal), and her white blood count had risen to 22,600.

The patient was taken to the operating room where empyema of the gallbladder was found and a cholecystectomy performed. The gallbladder was distended with approximately 150 cc. of purulent material and contained 25 stones ranging up to 1.8 cm. in diameter. The operative cholangiogram was normal.

Culture of the gallbladder contents grew out coagulase positive *Staphylococcus aureus* in pure culture. The organism was sensitive only to methicillin and vancomycin in a concentration of 1.5 gamma per cc. The patient's temperature returned to normal on the second postoperative day, and she was discharged on the sixth day following surgery.

Comment

In addition to the role of chemical factors (pancreatic secretions, concentrated bile) the importance of bacterial infection in the etiology of cholecystitis has been studied. Spread of infection to the gallbladder by hematogenous[2,3] and lymphatic[4] routes has been postulated. Direct infection from the intestine via the common bile duct has also been proposed, but this does not seem practical in the majority of cases in which an impacted stone blocks the cystic duct.

---

*Department of Surgery, University of Minunesota Hospitals, Minneapolis, Minnesota.

**USPHS Postdoctoral Research Fellow.

Dineen[5] has recently compared the theories of pathogenesis of gallbladder infection and concludes that the portal system is the most common route for delivering bacteria to the biliary tract. Small numbers of enteric organisms frequently enter the portal circulation from the intestinal tract, are removed from the blood by the reticuloendothelial system of the liver, and are excreted into the bile where they usually pass back into the intestine. In the presence of stagnant bile these organisms can multiply, stimulate leukocytic infiltration, and result in suppuration of the gallbladder.

The etiology of this patient's episode of cholecystitis can only be speculative. There was no evidence of a nidus of infection other than in the gallbladder, nor was there any history to suggest where she might have been exposed to a virulent strain of staphylococci. The possibility of such an atypical infection should be kept in mind when treating cholecystitis.

Summary

Cholecystitis in which coagulase positive *Staphylococcus aureus* can be cultured from the gallbladder is certainly unusual. Such an occurrence has not been reported previously.

Brain Scanning with Neohydrin 197-Hg[*]

LUTHER O. WIGDAHL, M.D.[**]
J. MICHAEL GILSON, M.D.[†]
EDWARD V. STAAB, M.D.[**]
MERLE K. LOKEN, Ph.D., M.D.[‡]
Minneapolis, Minnesota

We have concluded, as a result of our observations and in agreement with other investigators,[1,2,3,4,5] that brain scanning is a valuable diagnostic procedure for detecting and localizing brain tumors and certain other non-neoplastic lesions.

During the 15-month period prior to January 1, 1965, 432 brain scans were performed at the University of Minnesota and Veterans Administration Hospitals utilizing the radioactive isotope 197-Hg tagged to Neohydrin. In 388 of these 432 scans we reached a positive or negative conclusion. However, for reasons that will be elaborated in the discussion, the remaining 44 cases had to be considered indeterminate.

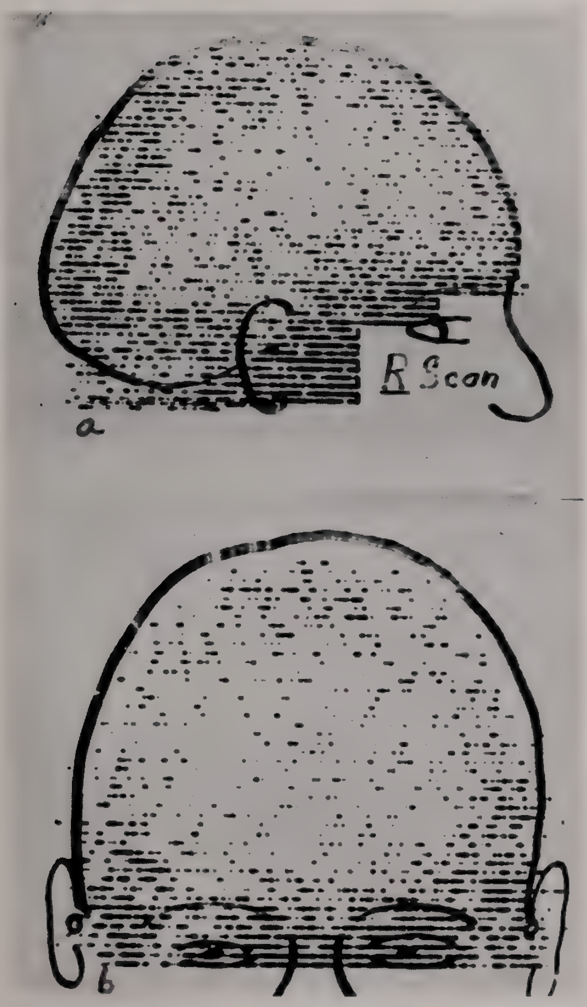

Fig. 1 — The normal brain scan. (a) Right lateral projection. (b) Frontal projection.

Procedure

Because of its simplicity, brain scanning is a procedure that can be performed with essentially no morbidity. 197-Hg Neohydrin is given intravenously in a dose of 10 microcuries per kilogram. Using the Picker magnascanner, we began scanning three to four hours after administration of the isotope and found that we were able to obtain two projections of the brain in about 1-1/2 hours. In certain cases additional projections or delayed scans at 24 hours were helpful.

The Normal Brain Scan

In a normal patient without circulatory embarrassment or significant renal impairment, about 90% of the isotope is cleared from the circulation in about five hours; therefore, as shown in the normal brain scan of Figure 1, only a small amount of circulating isotope is present in the major venous sinuses such as the sagittal and sigmoid. In addition, some normal accumulation of the isotope is seen in the temporal and occipital musculature as well as in the nasopharyngeal mucosal area.

The Abnormal Brain Scan

In a brain scan showing an abnormal state of the brain the isotope localizes in other than normal areas because there has been an alteration of the normal "blood-brain" barrier by pathological conditions. The large accumulation of black dots in the frontal area of the brain clearly demonstrates such an abnormality in Figure 2. Incidentally, this represents a large metastatic brain tumor, and the size of the lesion on the brain scan correlates well with the actual size of the tumor in well-demonstrated lesions such as this.

The first category of abnormality consists of neoplastic lesions, both primary and metastatic. Non-neoplastic lesions[6,7] comprise the second category and include intracerebral hematomas, acute and chronic subdural hematomas, and cerebral vascular accidents that result in appreciable ischemia or infarction. To the experienced observer, most of

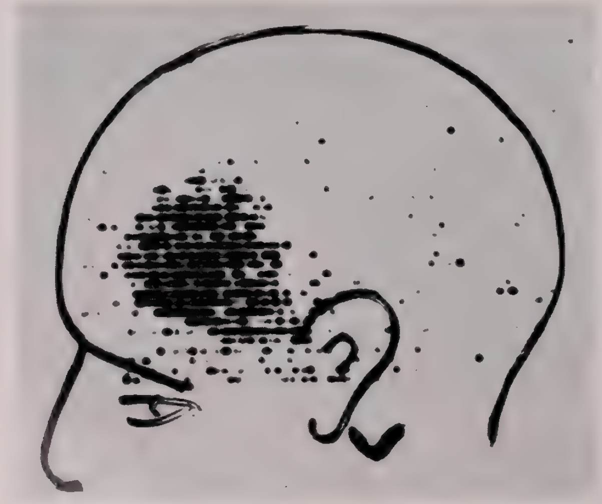

Fig. 2 — Positive brain scan, left frontal temporal area; metastatic tumor from undifferentiated carcinoma of the prostate.

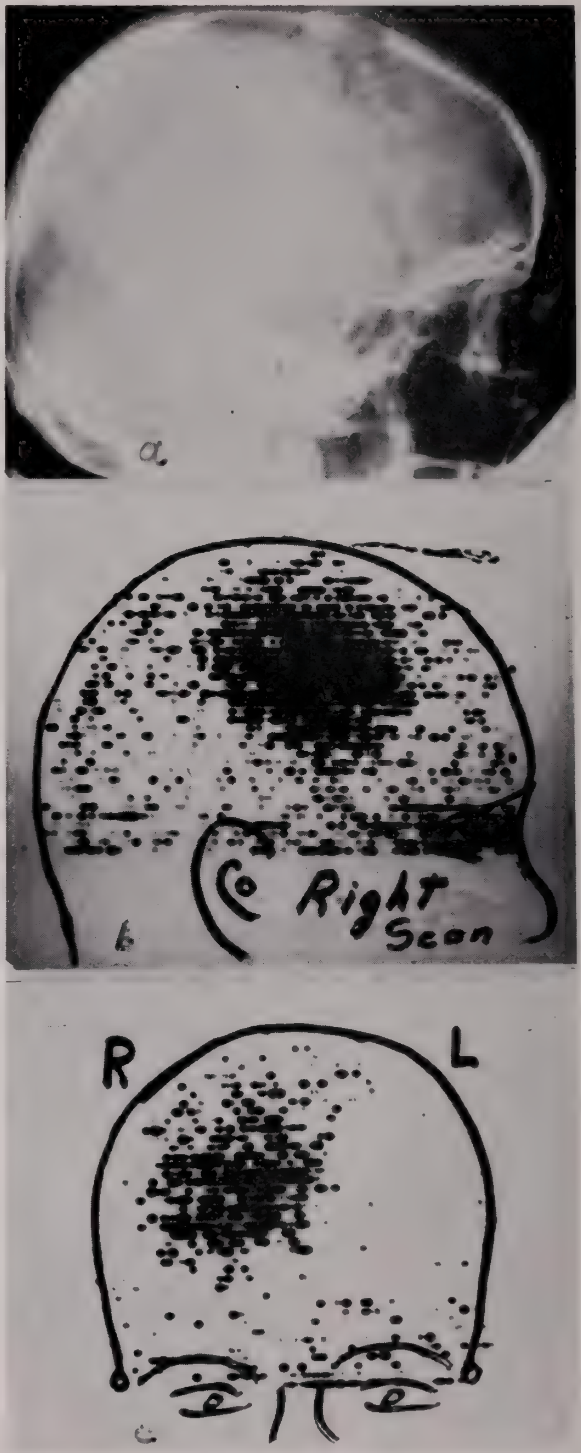

Fig. 3 — (a) Lateral skull demonstrating abnormal meningioma bone in parasagittal area. (b) Right lateral brain scan demonstrates large soft tissue component of meningioma, right frontal area. (c) Frontal projection.

these entities reveal a characteristic pattern; however, correlation with the clinical history and findings may be necessary for definitive interpretation.

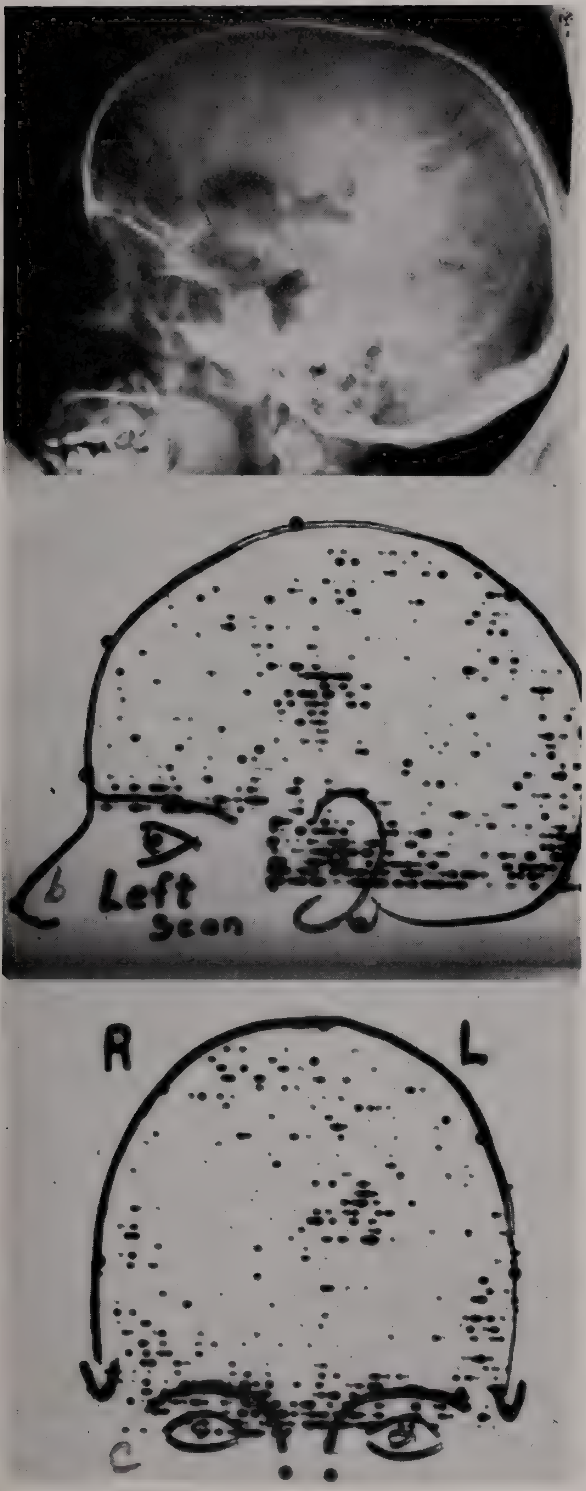

Fig. 4—Astrocytoma, Grade II. (a) Pneumoencephalogram reveals mass indenting roof of lateral ventricle. (b) Positive left lateral brain scan. (c) Frontal projection.

Brain Tumors

The lateral skull projection in Figure 3 reveals an abnormal area of bone in the frontal parasagittal area. The brain scan demonstrates well the large soft tissue component of the meningioma in the right frontal parasagittal area.

The lateral projection of the pneumoencephalogram in Figure 4 shows a mass indenting the roof of the lateral ventricle. The brain scan was also positive, giving good correlation with the localization seen on the pneumoencephalogram. This tumor proved to be a Grade II astrocytoma.

A few cases of brain tumor were demonstrated by brain scanning, although appropriate angiograms failed to reveal the lesion. The positive focus of black dots seen in the frontal parasagittal area in Figure 5 is an example. This proved to be a 3-cm. recurrent meningioma. The positive focus seen in the right cerebellar hemisphere in Figure 6 was also not localized by angiography and later proved to be a right cerebellar glioblastoma.

Metastatic tumors are also demonstrated in a high percentage of cases by brain scanning. A left carotid angiogram as shown in

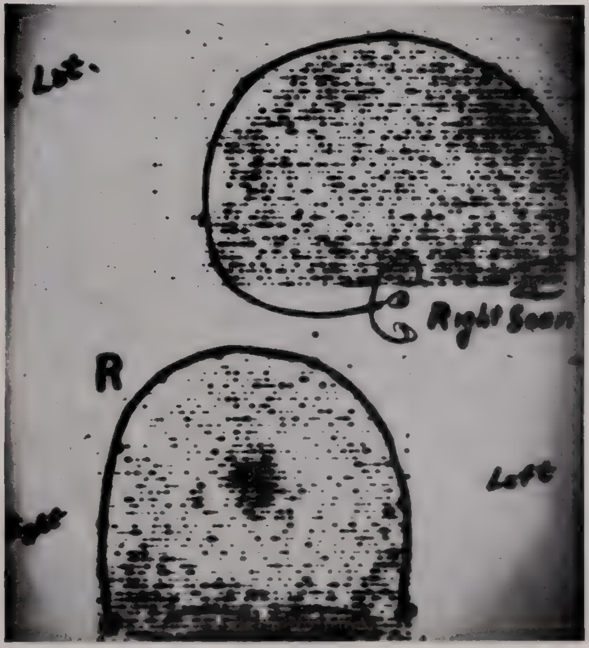

Fig. 5 — Recurrent meningioma, frontal parasagittal area, revealing a positive brain scan.

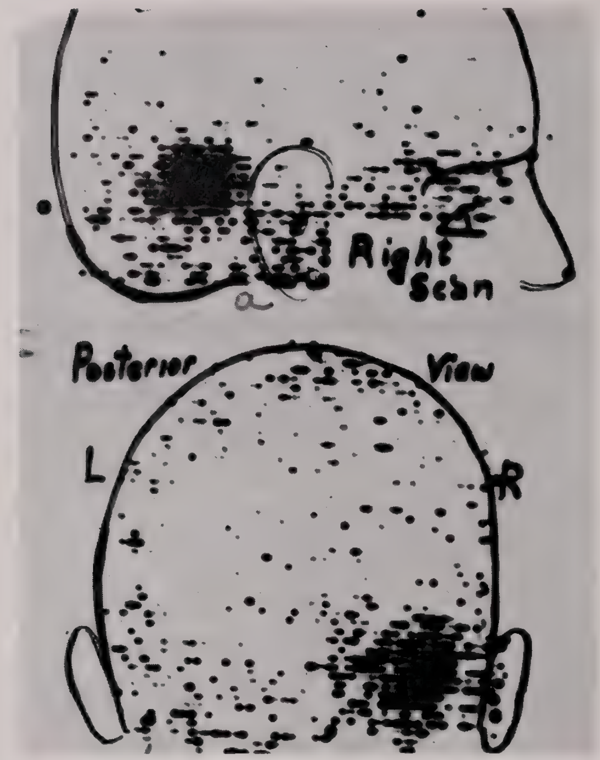

Fig. 6 — Glioblastoma, right cerebellum. (a) Positive right lateral scan. (b) Posterior view.

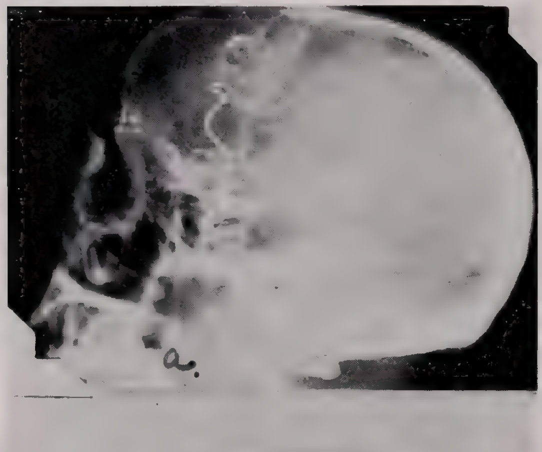

Fig. 7 — Metastatic tumor, left frontal lobe. (a) Demonstrated by left carotid angiogram. (b) Demonstrated by left lateral brain scan.

Figure 7 demonstrates a metastatic tumor in the left frontal lobe with abnormal vessels characteristic of tumor. The brain scan also localizes this lesion. In fact, when metastatic lesions were suspected, the brain scan was often the only special procedure performed. The 5-cm. metastatic lesion in the left cerebellar hemisphere, demonstrated in Figure 8, illustrates such a case.

Non-neoplastic Lesions

Positive brain scans were obtained of several patients having intracerebral and chronic subdural hematomas. As an illustration of this, the venous phase of a left carotid angiogram shown in Figure 9 reveals a left frontal subdural hematoma. The corresponding brain scan also reveals accumulation of isotope along the left lateral portion of the skull characteristic of chronic subdural hematoma. Another frequent abnormality giving a positive brain scan is cerebral throm-

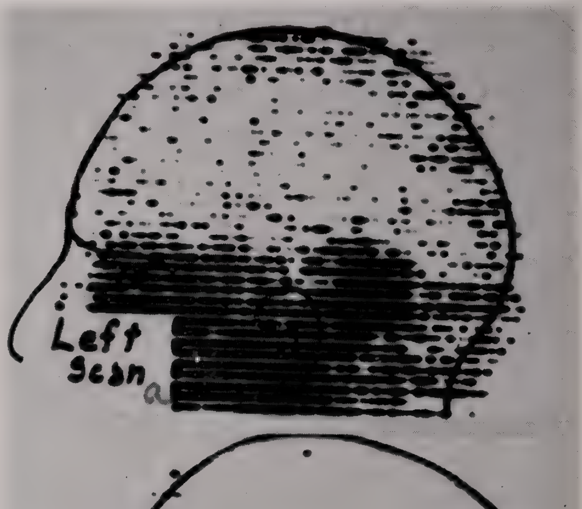

Fig. 8 — Metastatic tumor, left cerebellum. (a) Left lateral brain scan. (b) Right lateral brain scan.

bosis and infarction, as shown in Figure 10-a. The frontal projection of this scan, which is not included, reveals the typical diffuse pattern characteristic of middle cerebral artery thrombosis. A subsequent right lateral brain scan, Figure 10-b performed two months later, reveals complete clearing of this abnormal accumulation of isotope. This clearing after an interval of two to three months following the initial positive scan is typical of cerebral artery thrombosis. Such clearing would not occur with a neoplastic lesion.

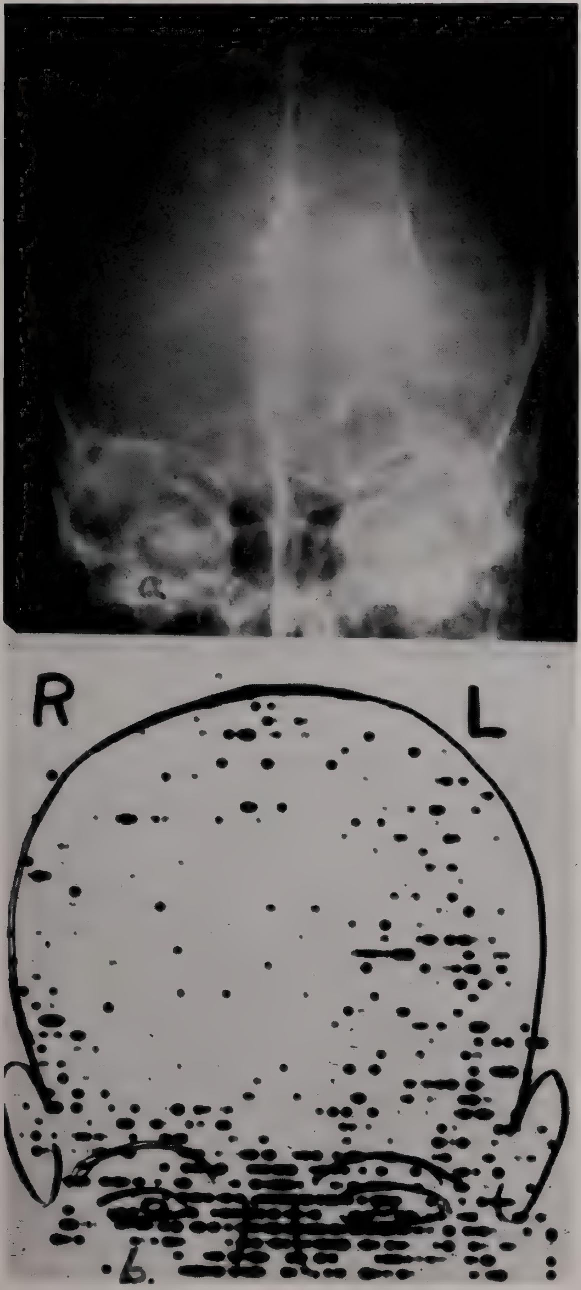

Fig. 9 — Large left frontal subdural hematoma. (a) Demonstrated by venous phase of left carotid angiogram. (b) Demonstrated by frontal projection of brain scan.

Discussion

Of the 45 primary brain tumors encountered in this series, approximately 85% revealed a positive brain scan. About 80% of the metastatic brain tumors revealed a positive scan. We encountered 30 positive scans of non-neoplastic lesions, with slightly more than ½ of these occurring in patients with cerebral vascular accidents.

Ten percent (44) of the brain scans were indeterminate.[8] In these cases we often noted moderately increased activity in basilar areas of the skull where adequate resolution of the lesion could not be obtained due to the normal activity found in areas of overly-

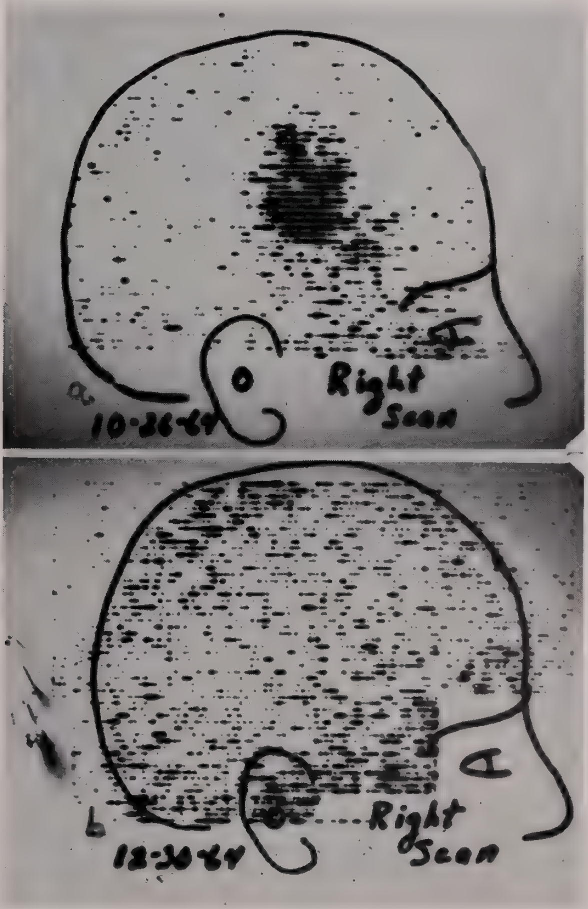

Fig. 10 — (a) Positive brain scan due to right middle cerebral artery occlusion. (b) Clearing of positive scan in same patient approximately two months later.

ing temporal or occipital musculature. Several of these cases of increased basal activity occurred in patients with extension of nasopharyngeal carcinomas to the brain. In others, slight areas of increased activity were noted, but a definitive impression could not be made either because the appropriate side of the brain had not been scanned or because needed additional projections had not been obtained. Another small group of scans was considered indeterminate because scanning had been performed at 24 hours only, with a total activity not great enough for reliable interpretation. A few cases showed slightly increased activity in areas of post-surgical cranial defects or soft tissue abnormalities overlying the skull and related to trauma or infection. With improved techniques and experience we believe this indeterminate group can be significantly reduced. However, even with the best technique, scans of questionable significance will be obtained, and experience indicates that these should be considered normal to avoid any danger of "over-calling".

Summary

Experience gained in the performance of 432 brain scans reveals that a high percentage of brain tumors can be detected and localized quite effectively by this procedure. The procedure has essentially no morbidity or adverse reactions. Brain tumors have been detected by this procedure when other methods have failed. In cases of metastatic brain tumors, the brain scan is often the only necessary special diagnostic procedure. In all cases of suspected brain tumor, brain scanning is a valuable adjunctive diagnostic procedure and, when possible, because of its low morbidity, brain scanning should be the first special diagnostic procedure attempted.

Acknowledgments

We wish to acknowledge with thanks the technical assistance of Mrs. Lucille Gomez, Miss Pearl Varian, Miss Norma Constantino and Mr. John Collis.

The Tobacco Tyrant

The American Cancer Society considers the physician to be the key figure in reducing deaths caused by cigarette smoking.

The Society's Board of Directors urged physicians to recognize the need for stopping smoking as an example to patients and teenagers. The doctors were called upon to participate with their professional organizations in attempting to reduce cigarette smoking and "personally to instruct those in their care about the health hazards of cigarette smoking."

The American Cancer Society also asked that the physicians devote time to telling young people about the dangers of cigarettes with "particular emphasis on the difficulties of breaking the cigarette smoking habit, once it is firmly established."

Chronic Ulcerative Colitis in Children

Reevaluation of Management*

HUGH B. LYNN, M.D.**
Rochester, Minnesota

TRADITIONALLY, MANAGEMENT of a case of chronic ulcerative colitis in childhood has been left to the gastroenterologist who treats adult cases. The line of reasoning apparently has been that chronic ulcerative colitis is a disease children must live through until after adolescence and maturity. Also, in all too many cases the nonintestinal symptomatology has clouded the true diagnosis and has been the focal point of the family's concern over a prolonged period of insidious progression of the disease.

Everyone is aware of the intermittency of chronic ulcerative colitis and of the possibility that each episode may be the final one leading to recovery. However, review of the cases arising in childhood (if not diagnosed in childhood) leads to grave concern that this disease is far from being as simple as might be hoped. The earlier the onset and the more persistent or frequently recurring the symptoms, the grimmer the outlook appears to be. As pointed out by Michener and associates,[1] cancer is a real threat. Perforation, toxic megacolon, and crippling arthritis are some of the obvious hazards. Failure to grow, mature, and enjoy living are less of a concern, statistically, but are very real considerations. Even when surgery has been recommended and consent granted, the operation undertaken has often been the one most likely to be acceptable to the parents and the family physician, rather than the one the surgeon and the pathologist sincerely believe is most likely to effect a cure.

It is my belief that any patient with chronic ulcerative colitis which is truly disabling for any prolonged period (in some cases as short a period as six months) and which shows advanced roentgenographic and proctoscopic changes may be a candidate for surgery. I am well aware that very few parents are going to agree to surgery after the first six months without adequate counsel from a qualified pediatrician or internist. Simply on the basis of the child's "being too young," the possibility of surgery is summarily dismissed in most consultations with the family. The possibility of cancer and, what is much more of a concern, the probability of death from that cancer once it arises, is glossed over as too harsh for parents' ears when the alternative is permanent ileostomy and total colectomy. Having watched preadolescent children adjust to an ileostomy (one seven-year-old refers to his as "Cyclops") and having watched them gain weight, grow in stature, participate in the athletic and social events of their schools, and very definitely discover the opposite sex, I am completely unwilling to shudder and cringe at the thought of an ileostomy in a child.

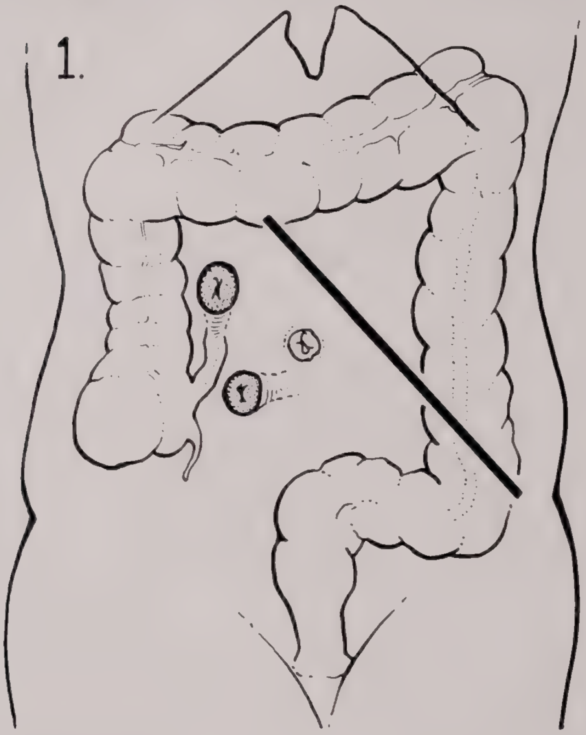
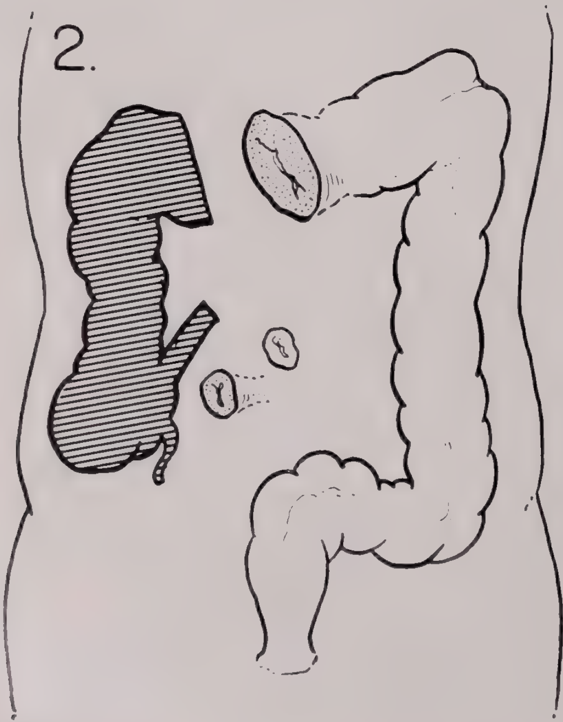
1.



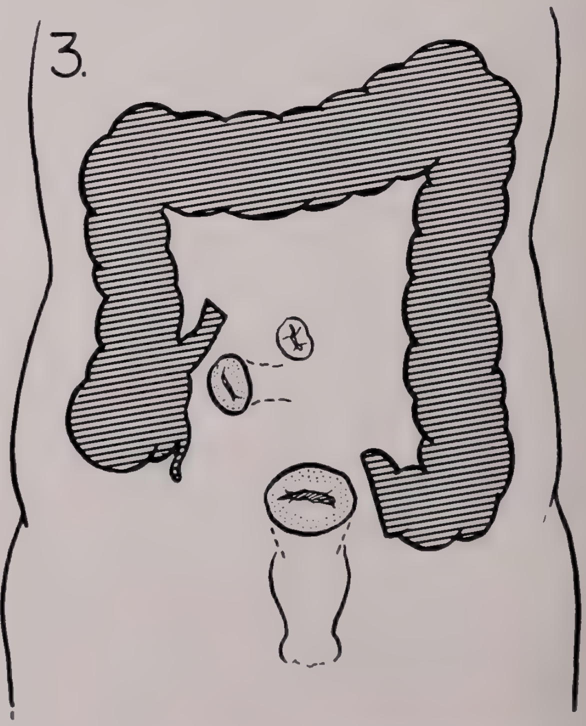
Certainly statistics indicate that the life expectancy is cut to approximately 20 years in more than 40% of these cases when the disease has its onset in childhood. In this era of increased and increasing longevity, 20 years is a very short time.

In the event that a surgeon is invited to consult on a child with chronic ulcerative colitis for other than profuse hemorrhage, toxic megacolon, perforation, and abscess formation, or complete wasting with chronic blood loss, decubitus ulcerations, or carcinoma (or more than one of these), various procedures are available that are recommended by many authorities. As I have suggested, a major portion of the surgery in childhood is of an emergency nature, and this is unfortunate.

2.



3.



Emergency Procedures

Double-barreled Ileostomy

The simplest possible operation in a patient in extremis is a double-barreled ileostomy (Figure 1). This is seldom successful in the fulminating cases and is rarely indicated in any patient who can stand anything more extensive. The disease has shown little or no abatement in my experience.

Ileostomy and Partial Resection

Even in desperately ill patients, an ileostomy can usually be accompanied by resection of terminal ileum, cecum, ascending colon, and at least part of the transverse colon (Figure 2). When possible, the removal of more colon is desirable. This is a more desirable procedure if only to eliminate later surgery in the right lower quadrant should the patient survive and the ileostomy be permanent.

Extensive Resection with Temporary Fistula

Even in the emergency cases it is beneficial to remove as much diseased bowel as possible. A resection as extensive as the patient can reasonably stand is the objective. This will vary with the circumstances and the surgeon. The rectosigmoid can be brought out as a mucous fistula below the incision when the patient's condition does not warrant total removal or turning in of the stump. This fistula can be excised at a later date but should *not* be left indefinitely (Figure 3). In our series carcinoma appeared in a defunctionalized stump 17 years after permanent ileostomy.

Elective Procedures

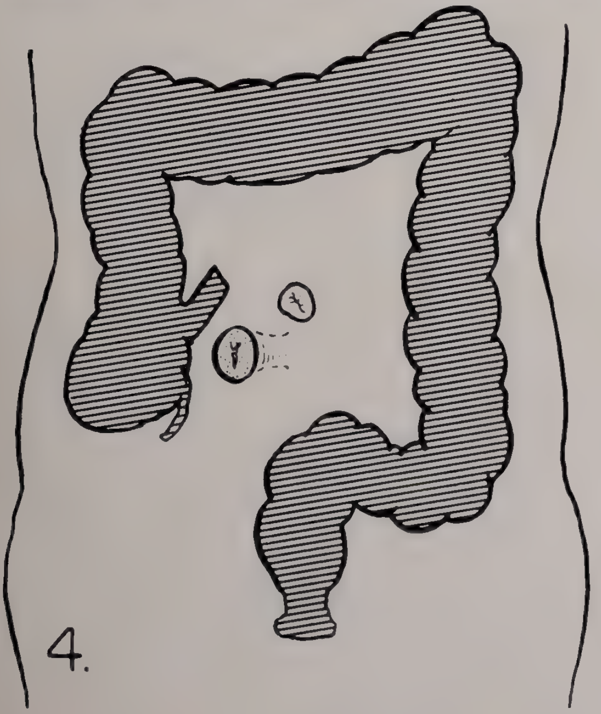
Eventually it is hoped that good surgical results and poor medical results with pediatric cases will lead to a change in attitude on the part of referring physicians and parents. This change can be advanced only by vigorous efforts on the part of surgeons to come to grips with the issue.

Ileostomy and Total Colectomy

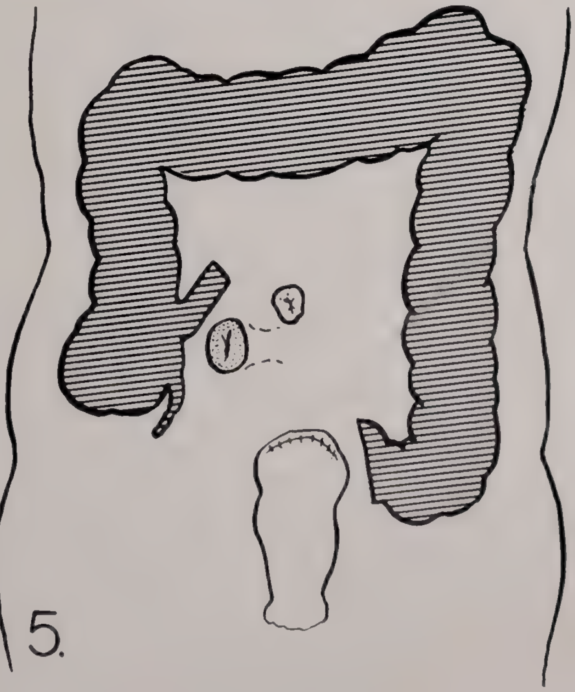
If there is obvious acute involvement of the rectum by the ulcerative process, little is to be gained (and much may be lost) by temporizing. A permanent ileostomy and total colectomy including the anus and rectum is indicated (Figure 4).

Resection with Saving the Rectum

In patients with moderate rectal involvement, there are possibly some advantages in saving the rectum for future reanastomosis. These advantages seem to me to be more theoretical than real, but the psychologic



4.

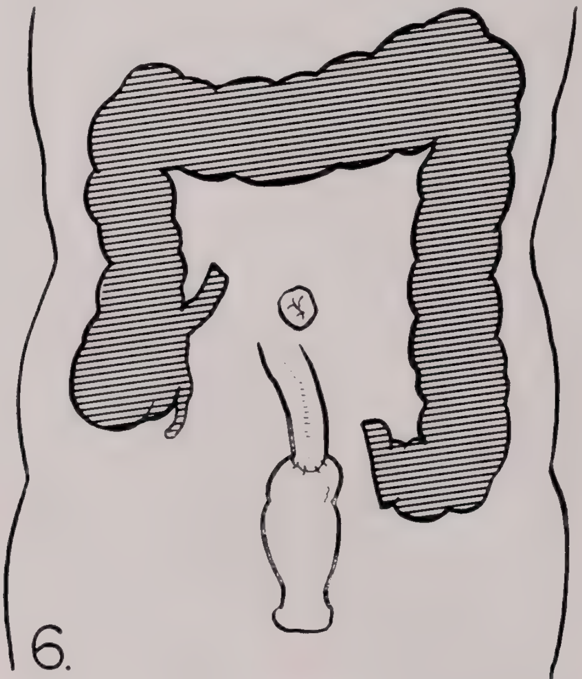


5.

value for the parents may justify it (Figure 5).

Anastomosis of Ileum to Rectum

When proctoscopy shows minimal involvement of the rectum, the idea of removing the colon and anastomosing the ileum to the rectum seems attractive (Fig. 6), at least to the parents and the referring physician. In my hands, this has been a fairly unsatisfactory substitute. The hazards of fistula, abscess, and obstruction seem to be unusually high. However, in one patient who returned for removal of the rectum and permanent ileostomy, at the insistence of the parents, the mother remarked that they could not have considered a permanent ileostomy 10 months before.



6.

Comments

In the past year I find I have employed all six operations, so that I cannot be too dogmatic about the choice of the elective procedures which have all too often been dictated by the emotions of the parents and the referring physician. I believe it is time that we, as intelligent physicians, make a more aggressive attack on this problem, both in the emergencies and in the elective cases, in order that the patient, the referring physician, and the parents can be adequately prepared both physically and emotionally for permanent ileostomy and total colectomy.

At this point it must be acknowledged that an ileostomy is not without complications and problems. In my own experience my ileostomy patients have actually had less difficulty with prolapse, stenosis, and retraction than have my colostomy patients.

Selecting the Site for Ileostomy

Whenever possible, the location of the site for ileostomy is now selected before operation by fitting the appliance of choice and allowing the patient to be active about the ward and making all his usual moves, so that it is possible to mark the position where it is most comfortable and where it is most likely to end up after the patient has climbed stairs, sat down and arisen from a chair, gotten in and out of bed, and so on. This usually results in placement of the stoma at a higher level with relation to the umbilicus than has been our custom.

Psychiatric Therapy

Within the last year, I have seen a 14-year-old boy with ileostomy and subtotal colectomy lie curled up in bed with no interest in ever getting up and leaving the hospital (his rectosigmoid was left as a mucous fistula because of the emergency nature of the surgery for perforation and pelvic abscess). Our psychiatric section had recommended his transfer to the open psychiatric floor for prolonged therapy. However, a pretty little nine-year-old girl who had been well prepared by intelligent parents and had taken her permanent ileostomy in stride was prevailed on to visit with this boy. Two visits did the trick. The knowledge that he was not alone, that he was not completely mutilated and defeated, and that others with his condition were taking overnight hikes, going to parties, and having fun was all that he needed. In three days he was out of the hospital and at home. Since then he has returned for the removal of the rectum and rectosigmoid. Everyone who knew him is impressed with the progress he has made in adjusting to his physical state and his relationship to an overly protective mother.

From many such experiences it would appear to me that children have an amazing and incomprehensible ability to adjust to their circumstances. Only parents and physicians who are revolted by the thought of an ileostomy could be so cruel and unreasonable as to permit a youngster to suffer years of disability and danger on the never-voiced hope that even if the malady does not clear up, perhaps ileostomy can be avoided until after the child's wedding and honeymoon. What an unfair and ridiculous way to view such a crippling disease

Summary

Chronic ulcerative colitis in childhood is a dangerous and dreaded disease. Palliation and temporizing during childhood in the hope of permitting normal growth and development are therefore deplored.

A strong plea is made for an earlier and more extensive surgical attack upon the diseased colon. An ileostomy is not too great a price to pay for freedom from such a horrible disease!

IT'S THE LAW

Doctor's License Suspended for Attempted Income Tax Evasion

The Board of Medical Examiners did not abuse its discretion in staying the revocation of a doctor's license for five years and placing him on probation during that period and in suspending his license for 180 days, where there was sufficient evidence to sustain its finding that he was guilty of unprofessional conduct in having been convicted, following a plea of *nolo contendere,* on two charges of attempting to evade payment of federal income taxes, which were offenses involving moral turpitude, a California intermediate appellate court ruled.

The doctor, who owned a hospital, had an arrangement with an insurance company to furnish medical and hospital services to Mexican workmen at a flat rate per month per laborer and an arrangement with a county to furnish medical and hospital services to people receiving Old Age Security. He exchanged the monthly checks he received from the insurance company and the county for cashier's checks, and the amount of those checks was not entered in the general income account kept by his bookkeeper from which his income tax returns were prepared. As the hospital needed money or the doctor needed money for living expenses, he would cash the cashier's checks. The doctor said that he followed this method to prevent his competitors from finding out how much income he received from the insurance company and the county.

The doctor contended that a conviction of a felony did not constitute unprofessional conduct unless the felony was one involving moral turpitude. The Board made a specific finding that the offenses of which the doctor was convicted involved moral turpitude. Although the doctor kept a record of the amounts received from the insurance company and the county in a place other than his regular income account, he did not tell the accountants that prepared his income tax returns about the income. There was sufficient evidence to support the inference that the doctor intentionally and for the purpose of personal gain filed false income tax returns and had thus been guilty of moral turpitude, the court said.

Acid-Base and Serum Electrolyte Values

in Clinical Practice[*]

ALFRED EICHENHOLZ, M.D.[**]
ROBERT O. MULHAUSEN, M.D.[†]
AUSMA S. BLUMENTALS, M.D.[‡]
Minneapolis, Minnesota

THE PRECISE evaluation of acid-base balance requires the analysis of arterial blood for pH, partial pressure of carbon dioxide (pCO_2) and true (arterial) plasma bicarbonate concentration ($[HCO_3^-]$).[1] Only in rare instances are these determinations performed routinely in the clinical laboratory. The published acid-base data indicate that the measurement of these three variables continues to be confined primarily to research laboratories.

The theoretical aspects of acid-base balance, especially the conceptual and terminological contradictions existing in this field, have been repeatedly discussed in the clinical

TABLE I

Outline of the Nomenclature and the Diagnostic Criteria on Which it is Based

	pH	pCO_2 mmHg	$[HCO_3^-]$ mM/L	$[HCO_3^-]_{7.40}$ mM/L
Mixed Metabolic-Respiratory Alkalosis	I	R	I-N-R	I
Mixed Metabolic-Respiratory Acidosis	R	I	I-N-R	R

TABLE 2

Patient	A	B
Hemoglobin gm%	7.5	19.5
pH	7.20	7.20
pCO_2 mmHg	70.0	70.0
$[HCO_3^-]$ mM/L	26.5	26.5
$[HCO_3^-]_{7.40}$ mM/L	23.1	18.6

Two patients with identical pH, pCO_2 and $[HCO_3^-]$ values which indicate severe respiratory acidosis. The $[HCO_3^-]_{7.40}$ value in patient A is within normal limits and he has an uncompensated respiratory acidosis. The $[HCO_3^-]_{7.40}$ value in patient B is definitely reduced, indicating a bicarbonate deficit, i.e., a state of mixed respiratory-metabolic acidosis.

literature of the past decade.[2-7] This polemic, which through its clarification and redefinition of certain basic concepts has been most valuable, has also unintentionally made this field somewhat esoteric. It appears as if these theoretical discussions have at least temporarily overshadowed the practical aspects of these measurements in clinical medicine.

The use of these measurements under clinical conditions has been greatly facilitated by the replacement of cumbersome methods with techniques which are well suited for use in a clinical laboratory. The clinical manifestations of acid-base disturbances have been incompletely defined, and concise criteria for the existence of a particular disturbance are generally lacking. The use of these measurements not only as a diagnostic tool but specifically as a therapeutic guide or a prognostic aid in clinical practice is only occasionally recorded.[8,9]

The analysis of an unselected sample of acid-base determinations performed in a routine clinical laboratory is the subject of this report. The simplicity of the technical procedure from the arterial puncture to the actual analysis is emphasized, as well as the usefulness of the direct measurement and the lack of validity of indirect estimates from serum electrolytes.

Method of Study

Materials

The materials for this study consisted of the clinical records of 212 patients in whom a total of 396 acid-base determinations were performed by the clinical laboratories of the Minneapolis Veterans Hospital during an arbitrarily selected time interval of six months (October 1963 to March 1964).

Methods

The acid-base determinations were performed at 38° C on anaerobic whole arterial blood using the Radiometer Astrup Microequipment; the pCO_2 and $[HCO_3^-]$ were obtained by the Astrup interpolation technique.[10] The values were corrected to the patient's temperature if it differed from 38° C, using the correction factors previously reported from this laboratory.[11] The actual $[HCO_3^-]$ were corrected for the buffering effect of whole blood to pH 7.40; these values are designated by the symbol $[HCO_3^-]_{7.40}$. When using the Astrup micro-equilibration technique, the intersect of the equilibration curve and pH value 7.40 is the $[HCO_3^-]_{7.40}$. The $[HCO_3^-]_{7.40}$ may also be calculated from an equation proposed by Van Slyke.[12] "Standard bicarbonate," proposed by Astrup,[10] differs from the $[HCO_3^-]_{7.40}$ in that it represents a correction of the actual bicarbonate concentration to a pCO_2 of 40 mmHg instead of to a pH of 7.40.

Sodium and potassium were determined by flame photometry, chloride by a modified method of Schales and Schales,[13] and CO_2 combining power by the method of Van Slyke.[14]

The Collection of Blood

According to an established routine at this institution, the arterial blood is obtained by the Junior house staff. The brachial artery is the most common site of puncture (80%), the femoral artery the next. The equipment used is a standard 10-cc. syringe and a 20-gauge disposable needle. The syringe is prepared by wetting the walls with heparin and filling the dead space of the syringe and the needle with heparin solution. Anesthesia of skin produced by injection (25-gauge needle) of 1% procaine solution minimizes a ventilatory response to the puncture. After the artery is entered percutaneously the syringe is allowed to fill under the influence of the blood pressure. Using this technique, there is as a rule no visible air bubble present; however, if one is present, it is expelled immediately after a specimen is obtained. The needle is left on the syringe after completion of the puncture and inserted into a rubber stopper; the entire syringe is immediately iced, and determinations are carried out as rapidly as possible (within one hour). Manual pressure is applied over the area of puncture for a minimum of eight minutes.

Interpretation of Values

The laboratory report contains the following values:

pH
pCO_2 (partial pressure of carbon dioxide)
$[HCO_3^-]$ (true plasma bicarbonate)
$[HCO_3^-]_{7.40}$ (true plasma bicarbonate corrected for the buffering effect of whole blood to pH 7.40)

The nomenclature which is in use at this institution is listed in Table 1. The diagnostic criteria are based on the four variables reported by the laboratory. Although the distinct separation of the various diagnostic categories is made possible by the $[HCO_3^-]_{7.40}$ value, this is only a partial justification for its use. The use of $[HCO_3^-]_{7.40}$ allows one to quantify changes in bicarbonate concentration which are in excess of that produced by blood-buffer shifts in response to variation in pCO_2. This is demonstrated by contrasting the values from two patients listed in Table 2, both of whom had severe obstructive pulmonary emphysema. Patient A was anemic; patient B had elevation of blood hemoglobin. Since the pH, pCO_2 and $[HCO_3^-]$ values are identical in both patients it may be concluded that their acid-base disturbance is of identical severity. However, the $[HCO_3^-]_{7.40}$ value in patient B shows that he has an absolute bicarbonate deficit and therefore a mixed respiratory-metabolic acidosis; the disturbance in patient A is an uncompensated respiratory acidosis.

There were occasional values which could be interpreted only with knowledge of the patients' clinical states. Examples of such acid-base values in two patients are shown

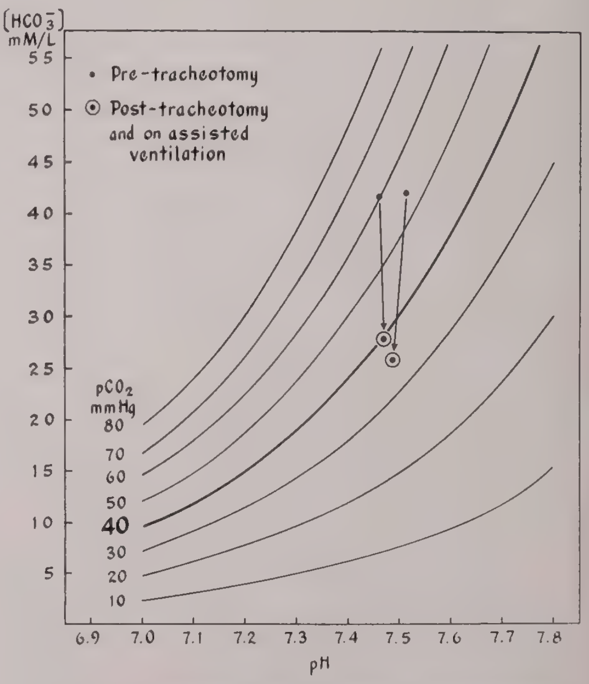

Fig. 1 — Note the nearly normal post-tracheotomy acid-base values, which are possible only while the emphysematous patients are on assisted ventilation.

on a bicarbonate-pH diagram in Figure 1. The post-tracheotomy values are nearly normal. These values were possible only because of the assisted ventilation.

Results

Of the 396 acid-base determinations, 354 were performed on blood samples obtained by direct arterial puncture. In 42 instances the blood was obtained through arterial cannulas during extracorporeal circulation* in open-heart surgery or renal hemodialysis.

The Reason for Acid-Base Studies

Abnormal respiration was the clinical sign most commonly used as an indication for an acid-base evaluation (132 instances); the presence of vomiting and/or diarrhea was the next most frequently used clinical indication (56 instances). An established routine during open-heart surgery and renal hemodialysis accounted for 49 determinations.

Predictability of Acid-Base Findings

The existence of a specific type of acid-base disturbance was predictable on clinical grounds in 166 instances (42%); however, in 128 of these an abnormal serum electrolyte pattern was equally suggestive. In an additional 57 cases (14%) a combination of clinical findings and serum electrolyte patterns was indicative of a specific type of acid-base disturbance. In 124 (31%) the findings could not be predicted from available clinical information or serum electrolyte pattern. However, although the type of acid-base disturbance was predictable in 223 instances, there was not a single case in which the precise acid-base values could be estimated from the clinical serum electrolyte findings.

Clinical States and Acid-Base Balance

No specific acid-base abnormality was exclusively associated with a single clinical state. The distribution of acid-base findings among broad categories of clinical abnormalities is shown in Table 3. However, among the various acid-base disturbances certain specific clinical states were predominant: obstructive pulmonary emphysema in respiratory acidosis, pyloric obstruction and thiazide administration in metabolic alkalosis, chronic glomerulonephritis in metabolic acidosis and postoperative state after major surgical procedures in mixed metabolic respiratory acidosis.

Lack of Association Between Acid-Base and Serum Electrolyte Values

The distribution of the 396 acid-base values is shown on a bicarbonate-pH diagram in Figure 2. The shape of the areas occupied by the various types of disturbances is formed by a line connecting the extreme points in each group. In 187 instances, serum electrolytes were determined on the day of the acid-base determination; the distribution of the 187 acid-base determinations is shown in

TABLE 3
The Distribution of the Various Acid-Base Disturbances Among Broad Categories of Clinical States

	Respiratory Acidosis	Metabolic Alkalosis	Normal	Respiratory Alkalosis	Metabolic Acidosis	Mixed Respiratory-Metabolic Acidosis

---

*See Test Your Word Score Page 447.

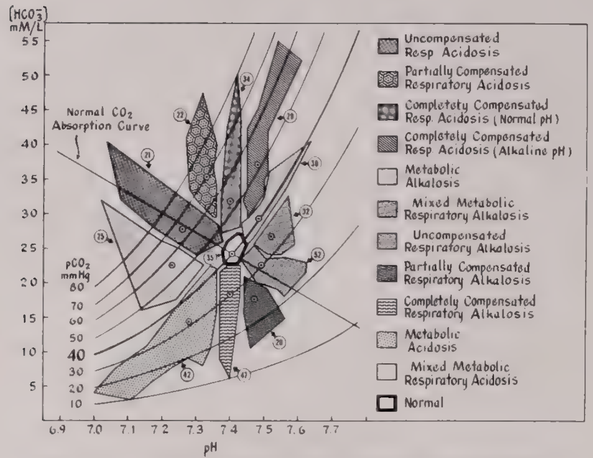

Fig. 2 — The shape of the areas representing the various acid-base disturbances was formed by a line connecting the extreme points in a given group. The round circle within each area is the mean value and the figures are the number of determinations in each group.

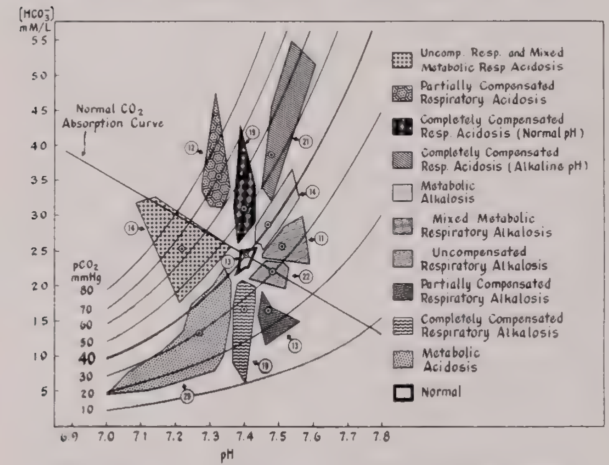

Fig. 3 — In this group of 187 acid-base measurements serum electrolytes (Fig. 4) were determined on the same day. Note that because of smaller number, two groups, mixed metabolic-respiratory acidosis and uncompensated respiratory acidosis, are combined.

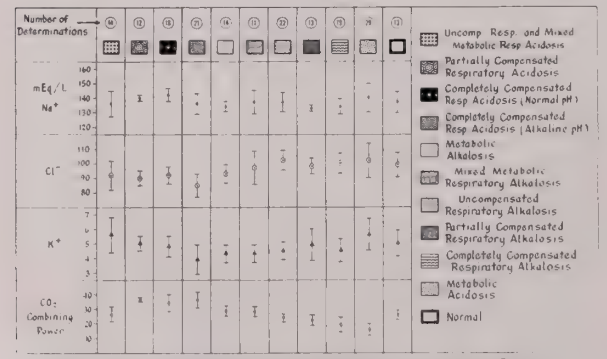

Fig. 4 — The mean and range of serum electrolyte concentrations determined on the same day as the acid-base measurements. The distribution of the corresponding acid-base values is shown in Fig. 3.

Figure 3, and the serum electrolyte concentrations corresponding to each acid-base group are shown in Figure 4. Table 4 lists the mean values and ranges for the data shown in Figures 2 and 3. The two groups, mixed respiratory-metabolic acidosis and uncompensated respiratory acidosis, are combined.

These data fail to reveal a serum electrolyte pattern characteristic of a specific type of acid-base disturbance. In general the CO_2 combining power appeared to parallel the plasma bicarbonate concentration; however, in many instances this determination proved to be most misleading. The serum potassium was elevated in most but not all instances of acidosis and was frequently reduced in the presence of alkalosis. This tendency to an inverse relationship between potassium concentration and pH value was not related to the primary nature of the acid-base disturbance, i.e., whether respiratory or metabolic. A normal serum electrolyte pattern was not uncommon in each specific type of acid-base disturbance. Attention is called to the occurrence of abnormal serum electrolytes among the patients whose acid-base values were normal.

Discussion

At present, percutaneous arterial punctures for acid-base analyses are being performed at this hospital at an annual rate exceeding one thousand, most of them by the Junior house staff using the described technique. The absence of morbidity in several thousand arterial punctures demonstrates the safety of the procedure. We believe that the application of manual pressure over the puncture area for a minimum of eight minutes is a major factor in the prevention of leakage.

The lack of specificity of serum electrolyte patterns in the diagnosis of acid-base disturbances is self-evident from the data presented. Although the type of acid-base disturbance was predictable in some patients, the assessment of its severity was usually not possible on the basis of the serum electrolytes. Measurement of severity is basic to the selection of proper corrective measures, the intensity with which these are applied, and the evaluation of the response.

Two examples of recovery from a severe disturbance in acid-base balance not reflected in serum electrolytes are shown in Table 5. Patient A was a 67-year-old man admitted for the first time in severe respiratory distress with clinical findings of severe obstructive pulmonary emphysema and decompensated cor pulmonale. Patient B was a 40-year-old man with renal amyloidosis secondary to extensive tuberculosis. On admission this patient was hypotensive, disoriented, and hyperventilating severely. Both patients recovered; in both therapy was guided by serial acid-base measurements.

Quantitative approaches to therapy of disturbances in acid-base balance have been proposed.[15,16] These are applicable primarily to abnormalities in which there is a bicarbonate deficit, and are essentially guides for the replacement of an existing deficit as calculated from the plasma values. The desirability of therapy appropriate to the needs

TABLE 4

The changes in the serum electrolytes do not reflect the progressive reduction in pCo_2 in patient A and the marked improvement in the metabolic acidosis of Patient B.

of the individual patient is self-evident. The data available in the literature are an inadequate basis for such ideal therapy, indicating a definite need for additional studies in this area.

Little is known at present about the effect that a disturbance of hydrogen-ion metabolism may have upon the course of a given clinical entity. It is generally stated that the range of blood pH compatible with life is 6.80 to 7.80;[17] however, the mechanisms through which values outside this range become incompatible with life are obscure. The need for extensive clinical studies in order to define any correlations which may exist between clinical symptomatology and the underlying disturbance in hydrogen-ion metabolism cannot be overemphasized.

The occurrence of disturbances in hydrogen-ion metabolism in a variety of unrelated clinical states has been demonstrated in this study. The rapidity with which an acid-base disturbance may develop is not widely recognized. On many occasions we have observed a reduction in bicarbonate concentration exceeding 50% of the original value during an interval of several hours. A spontaneous gain in bicarbonate concentration of similar magnitude has also occurred rapidly, but with less frequency. Changes in ventilation are followed by an almost instantaneous change in pCO_2 and therefore rapidly reflected in the acid-base determinations.

Abnormal respiration (hypo-or hyperventilation) is the clinical manifestation which most clearly indicates the presence of an acid-base disturbance. The respiratory abnormality may occur as a consequence of such disturbance or may be its cause. It should be noted that approximately 90% of the abnormal acid-base values observed were associated with an abnormal pCO_2. Other clinical manifestations which were thought related to the existing acid-base disturbance were twelve instances of tetany (overt clinical tetany three, positive Chvostek's sign nine) in patients with primary respiratory or metabolic alkalosis, and seven instances of hypotension responsive to correction of acidosis.

Almost two thirds of the cases of chronic respiratory acidosis in patients with obstructive pulmonary emphysema were completely compensated as indicated by a normal or alkaline pH. This finding is in conflict with a suggestion advanced in the literature[6] that complete compensation does not occur. Instances of alkaline pH in such patients have been reported previously.[18] The hospital mortality rates among these patients with pulmonary emphysema were of interest since they indicate the potential usefulness of the acid-base determinations as a prognostic aid. The mortality rate was 60% in the group with mixed respiratory-metabolic acidosis and uncompensated respiratory acidosis, 31% in the group with partially compensated respiratory acidosis, and 16% in the group with completely compensated respiratory acidosis (pH normal or alkaline).

As might be expected, the highest mortality, over 80%, was observed in patients with mixed respiratory-metabolic acidosis, since this disorder reflects the functional failure of the two organs primarily concerned with acid-base regulation, viz., the lungs and the kidneys. The occurrence of this disturbance in patients after major surgical procedures is a serious complication.

Summary

Abnormalities in the hydrogen-ion metabolism occur in a variety of unrelated clinical conditions, both medical and surgical. The specific type and the severity of an abnormality in hydrogen-ion metabolism cannot be accurately diagnosed from serum electrolytes and require the determination of pH, pCO_2 and bicarbonate concentration, the latter performed on arterial blood.

Arterial puncture is not a difficult technical procedure, and the diagnostic precision of acid-base determinations from arterial blood make it a very desirable clinical test.

Congenital Cystic Dilatation of the Common Bile Duct

Preoperative Diagnosis by Intravenous Cholangiogram.

R. G. CARLSON, M.D., F.A.C.S.*
Anoka, Minnesota
W. W. GLAS, M.D., F.A.C.S.**
Eloise, Michigan

THE DIAGNOSIS OF congenital cystic dilatation of the common bile duct has been considered preoperatively in only 30% of the 403 cases reported in the world literature.[1,2,3] The mortality of this disease, when multiple operations have been performed, is 69% and only 9% with primary anastomosis.[4] Because most surgeons encounter congenital cystic dilatation of the common duct without previous personal experience and without warning,[5] it is obvious that all surgeons who operate upon the biliary tract should be familiar with the treatment of these cysts.

Vater, in 1723, first reported a congenital cyst of the extrahepatic biliary tree. Judd and Green found one in every 17,381 cases of biliary tract surgery. Smith noted two cases in 757,000 hospital admissions. Alonso found 403 cases in the world literature, constituting an average of one per 250,000 hospital admissions.

These cysts have been reported in stillborn infants and in persons of all ages up to 65.[7]

A well defined classification of choledochal cysts has not been established. Though Alonzo referred to cystic dilatation of the common bile duct as being the most common, he observed three cases of congenital diverticula and four of congenital choledochocele within the duodenal wall. Gross,[4] in describing his cases, referred to congenital weakness of a portion of the common bile duct associated with distal obstruction, which could be either congenital or acquired.[5]

*Formerly Rice Memorial Hospital, Willmar, Minnesota. Now at Anoka, Minnesota.

**Chief of Surgery, Wayne County General Hospital, Eloise, Michigan (deceased).

Clinical Symptoms

The classic triad of abdominal pain, mass, and jaundice was present in 20 to 60 per cent of the reported cases.[5] Children most often have obstruction with jaundice, whereas adults usually have pain or pancreatitis.

The differential diagnosis[4,5] includes echinococcal cysts of the liver which remain stationary in size, are rarely painful, and can be confirmed by eosinophilia and complement fixation tests; cholelithiasis in children is rare unless hemolytic disease is present; abdominal neoplasms are stationary in size, solid, irregular, and without jaundice; congenital atresia of the bile ducts becomes evident in neonates; congenital cysts of the liver are usually small, multiple and associated with cystic disease, and pancreatic cysts are more to the left of the abdomen.

X-ray Findings

Flat plates of the abdomen may reveal a right upper quadrant mass displacing the bowel, and barium in the stomach may show the duodenum displaced inferiorly and to the left.

An oral cholecystogram frequently shows nonvisualization, whereas intravenous cholangiograms may be diagnostic if the serum bilirubin is normal. The terminal common duct is usually narrowed, but there is marked cystic dilatation with normal hepatic radicals. The cyst may be confused with the normal gallbladder, but the pointed end of the cyst adjacent to the ampulla of Vater suggests that the abnormality is not a gallbladder. Jesseman[8] warns that one may be misled by the presence of contrast media in the upper portion of the duodenum; therefore, concurrent intravenous cholangiography and upper gastrointestinal x-rays are essential to rule out this possibility.

Treatment

Partial or complete excision, first done by McWhorter in 1922, is especially suitable for a diverticulum type of choledochal cyst, having the lowest postoperative morbidity but a high operative mortality ranging up to 50 per cent.[5]

Roux-en-Y cysto-jejunostomy

Ferris[3] and Maingot,[9] because of the low incidence of postoperative cholangitis, prefer the Roux-en-Y procedure; Ravitch[10] rec-

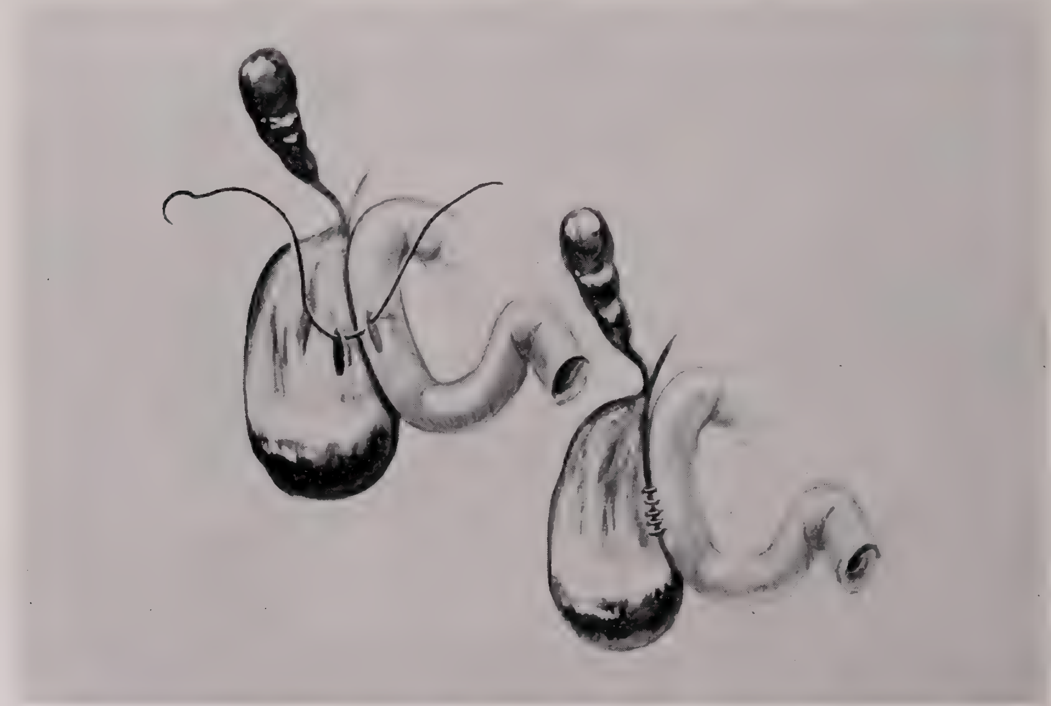

Fig. 1 — Artist's view of choledococysto-duodenostomy in a four-year-old child. (The anastomosis was more dependent than illustrated).

ommends it as the treatment of choice in large cysts. Others advise concurrent excision of the redundant portion of the sac.

Cysto-gastrostomy

Excision of the cyst and replacement with a gastric tube pedicle is a unique procedure popularized by Heimlich,[11] having the advantage of the Roux-en-Y procedure; in addition, it reduces peptic ulceration by retaining the bile flow into the duodenum instead of the jejunum.

Other Procedures

A gallbladder bypass can be used if excessive adhesions are present near the cyst, and a choledochocele is best corrected by a simple incision into the duodenal wall. Choledochorraphy is an inadequate primary procedure because it fails to correct the common duct obstruction.

Cysto-duodenostomy

This procedure is best for *small* retroduodenal cysts in which the dependent portion of the cyst can be anastomosed to the duodenum (Figure 1). Numerous cases of postoperative occlusion of these anastomoses have been reported; up to 30 per cent of these patients have postoperative recurring pain, fever, or cholangitis. Despite this, Gross[4] and many other surgeons advise this procedure because it carries a low operative mortality.

All three of our cases were treated in this way.

Case Reports

Case 1

This four-year-old Negro presented herself with a two-week history of itching, yellow eyes, mild intermittent abdominal pain of two weeks duration, but no nausea or vomiting. Two previous episodes of "yellow eyes," when the child was two and three years old, were treated at home by her grandmother.

Physical examination showed an icteric child in no apparent distress. A tensely cystic abdominal mass extended four finger-breadths below the right costal margin. The stools were clay-colored. The hemoglobin was 12.4 grams and the leukocyte count was 9,350. The urine contained bile and the direct serum bilirubin was 8.4 mgm.% with a total of 11.4 mgm.%. The alkaline phosphatase was 40 King Angstrom units; the serum glutamic transaminase 70 units; the cephalin flocculation 0 units; the serum protein 3.5 grams% of albumin and 3.8 grams% of globulin. Upper gastrointestinal barium roentgeno-

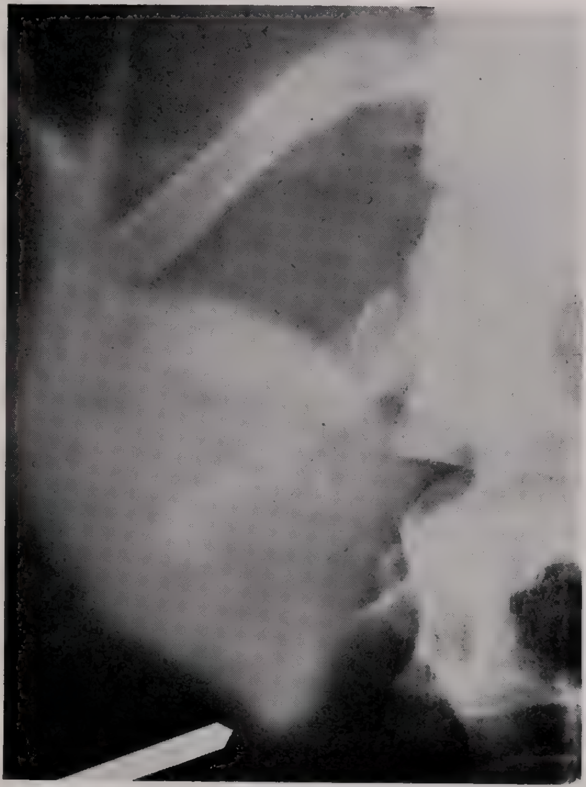

Fig. 2 — Intravenous cholangiogram of choledochal cyst. — Note the *pointed tip of the medial edge of the cyst.* Contrast increased by artist's retouching.

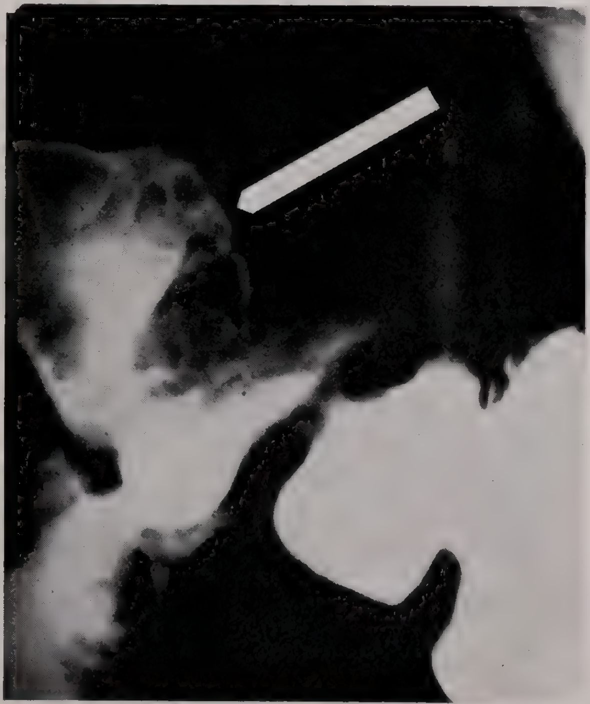

Fig. 3 — Postoperative upper gastrointestinal barium roentgenogram illustrating patency of the choledocho cysto-duodenal anastomosis. Arrow points to cyst.

grams showed duodenal compression to the left.

A preoperative diagnosis of choledochal cyst was made. Through a right subcostal incision a 10 x 8 x 6 cm. cyst containing 700 cc. of green bile was noted adjacent to the right side of the duodenum (Figure 1). A choledochocysto-duodenostomy was done. Radiography on the second postoperative day showed gas in the cyst. The patient was discharged on the eighteenth postoperative day, having had an uneventful recovery. Fifteen months later she was still free of symptoms.

Case 2

This 34-year-old negro mother gave a two-month history of chills, fever, jaundice, light stools and dark urine. Intermittent right upper quadrant abdominal colic had been present for six months, associated with vomiting and a 25-pound weight loss.

The physical examination showed icteric sclerae and right costal-vertebral tenderness, but no abdominal mass or tenderness. The stools were clay-colored.

The hematocrit was 46%; leukocyte count 4100; bile in the urine; direct serum bilirubin 9.5 mgm.%, with a total of 12.5 mgm.%; alkaline phosphatase of 22 King Angstrom units; cephalin flocculation 3+; serum protein 4.8 grams of albumin and 4.4 grams of globulin; serum glutamic oxy-transaminase 188 units; and a prothrombin time of 60%. Percutaneous needle liver biopsy showed biliary obstruction.

A choledocho-cysto-duodenostomy and a cholecystectomy were done for the 5-cm. retroduodenal choledochal cyst. In the immediate postoperative period bleeding from an aberrant artery caused shock requiring re-operation and ligation of the artery. The remainder of the postoperative convalescence was uneventful. An upper gastrointestinal roentgenogram five months later showed filling of the choledochal cyst.

Case 3

A 30-year-old white mother had post-prandial epigastric distress of four years duration. She had some fatty food dyscrasia and gas, but no nausea, vomiting, weight loss, jaundice, or abnormally colored stools or urine. A cholecystectomy had been done 18 months previously because of nonvisualization of the gallbladder by orally administered dye. No stones were found, but the common duct was reported to measure 3 cm. in diameter.

Physical examination showed a thin, white female with right upper quadrant tenderness. There was no icterus. Laboratory determinations were normal and of no diagnostic significance. Barium roentgenogram of the stomach and duodenum was also normal. Intravenous cholangiogram showed a slightly dilated common duct and a 3 x 8 cm. large sac with a *pointed tip* on the medial edge suggesting a choledochal cyst rather than a gallbladder (Figure 2).

A choledochocysto-duodenostomy was performed. The pointed medial tip of the cyst was found to be one cm. from the ampulla of Vater and a two-mm. probe could not be passed from the cyst through the sphincter of Oddi.

The postoperative course was uneventful. An upper gastrointestinal barium roentgenogram six weeks postoperatively showed barium reflux into the cyst (Figure 3). The patient has been free of symptoms except for occasional right upper quadrant abdominal pain following the eating of peanuts or coarse foods. Recently the patient had a normal pregnancy and delivery.

Comments and Conclusions

Cystic dilatation of the common duct, though rare, may be encountered by anyone performing biliary surgery. Perhaps one should routinely obtain an intravenous cholangiogram whenever a cholecystogram shows nonvisualization.

The classic triad of intermittent jaundice, abdominal pain, and a mass suggesting choledochal cyst is not uniformly evident.

Because of the relatively low operative mortality, choledochocysto-duodenostomy seems to be the treatment of choice.

Papyrus Ebers[*]

To Extract Slivers

In the minor triad — bites, burns, and slivers, slivers were by no means ignored or neglected in ancient Egyptian therapeutics. The Ebers Papyrus lists a variety of salves for extracting splinters from tender flesh.

What to do to Draw Out Splinters in the Flesh

The per-baibait-bird-with-Honey
Apply thereto.

Another

Worms' blood, cook and crush in Oil;
Mole, kill, cook, and drain in Oil;
Ass's dung, mix in Fresh Milk
Apply to the opening.

Another

Skull-of-the-Shadfish, cooked in Oil
Apply to the point of the splinter. Thereby it comes out.

Another

Incense
Dough
Sea-salt
Wasp's dung
Fat

Another

Red-lead
Wax
Apply thereto. It draws the matter out.[**]

administration

normal activity...

promptly...

In children with diarrhea prompt symptomatic control is usually urgently indicated to relieve cramping and to prevent dehydration.

Lomotil halts precipitous progress through the intestines and controls diarrhea with notable promptness, safety and effectiveness.

Experimental evidence[1] has shown that Lomotil is more efficient in this regard than morphine without the latter's manifest disadvantages. In roentgenographic study[2] Lomotil slowed gastrointestinal propulsion within two hours.

At the same time, by diminishing overstimulation of the intestines, Lomotil relieves the abdominal cramps and discomfort so distressing to youngsters.

Lomotil gets children off toast and tea and back to normal diets and normal activity with gratifying celerity.

with LOMOTIL® liquid/tablets

Each tablet and each 5 cc. of liquid contains:

diphenoxylate hydrochloride (Warning: may be habit forming)	2.5 mg.
atropine sulfate	0.025 mg.

Dosage: For full therapeutic effect—Rx full therapeutic dosage. The recommended initial *daily dosages*, given in divided doses, until diarrhea is controlled, are:

Children:

3 to 6 months	3 mg.	(½ tsp* t.i.d.)
6 to 12 months	4 mg.	(½ tsp. q.i.d.)
1 to 2 years	5 mg.	(½ tsp. 5 times daily)
2 to 5 years	6 mg.	(1 tsp. t.i.d.)
5 to 8 years	8 mg.	(1 tsp. q.i.d.)
8 to 12 years	10 mg.	(1 tsp. 5 times daily)

Adults: 20 mg. (2 tsp. 5 times daily or 2 tablets 4 times daily)

*Based on 4 cc. per teaspoonful.

Maintenance dosage may be as low as one fourth the therapeutic dose.

Precautions: Lomotil, brand of diphenoxylate hydrochloride with atropine sulfate, is an exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates. The subtherapeutic amount of atropine is added to discourage deliberate overdosage.

Side Effects: Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia.

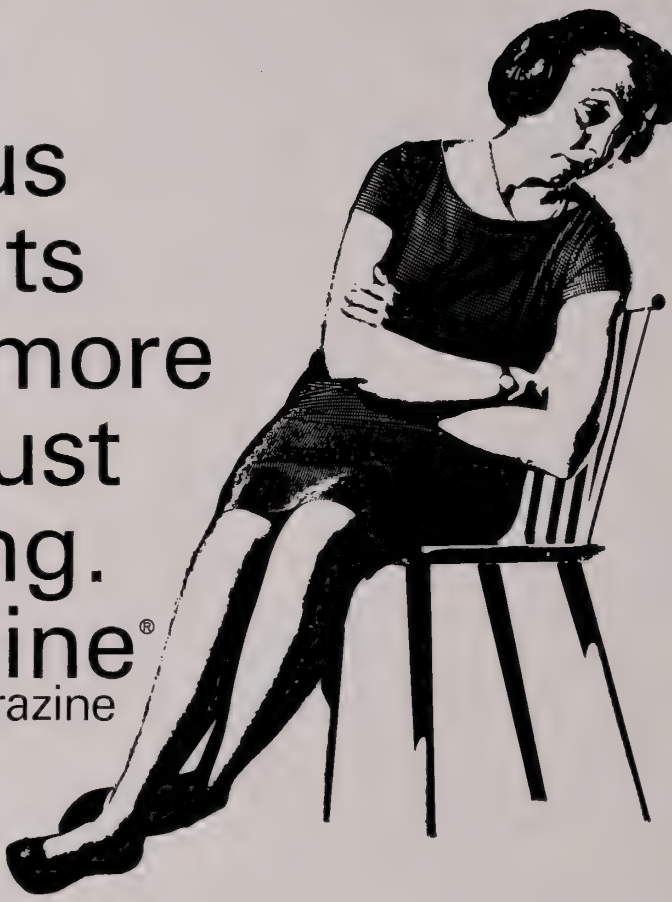
SEARLE

Research in the Service of Medicine



Many anxious patients need more than just calming. Stelazine®
brand of trifluoperazine
offers true tranquilization.

Sedative or muscle relaxant-type tranquilizers are often all that's needed for patients with temporary situational anxiety. But in the many patients whose anxiety presents a continuing problem these agents are limited by their generalized dulling effects.

'Stelazine' can attack anxiety directly without producing annoying dulling effects. On 'Stelazine', patients can react more normally to day-to-day stress yet remain alert, able to carry on their normal activities.

Contraindicated in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems. Before prescribing, see SK&F product Prescribing Information.

SK&F Smith Kline & French Laboratories, Philadelphia

Hostility

SOME PHYSICIANS would like to concentrate their practice upon patients suffering from organic disease. They have been taught that a given constellation of symptoms and signs, plus corroborative laboratory studies, lead to a given disease which, when defined, can then be treated. What is not so carefully expounded is the fact that the identical symptoms and many of the other findings may stem not from the suffering organ but from the suffering ego. Some decry the neurotic patient as a nuisance cluttering up the office and unnecessarily filling the hospital beds. He is rejected by "You're not sick—it's all in your head" or repudiated by other means.

The patient whose nausea and vomiting are due to anorexia nervosa can vomit just as much and as hard as the intestinally obstructed patient. The sufferer from cardiac neurosis can be as equally incapacitated as the victim of valvular disease.

Therapy of such a patient is difficult and time-consuming, and the results are painfully slow. But success with these nervous individuals can mean many years of life—neurotic life to be sure; but this is beyond our purview.

Alan Challman in his article, "Hostility and Disease" in this issue,* discusses several facets of the problems the physician encounters with emotionally disturbed people. He examines in detail the factor of hostility that plays such a dominant role in human relations and is such a major impediment to the intimate patient-doctor relationship. Challman points out that not all the hostility comes from the patient; the physician too may be acting out (in a carefully camouflaged way of course) what amounts to hostility. It behooves the physician to study this fact of human behavior, especially to recognize and control his own hostility. The doctor who despises the neurotic patient may be reacting to his own inability to handle such a problem. He may envy the mechanic leaning over the knocking automobile engine who can say "The number 4 rodbearing is shot"; who can replace that part, and so stop the engine from knocking. It is because of the neurotic patients, the unpredictable humans who are the doctors' patients, that physicians are not mere mechanics. The key to many medical problems lies in recognizing emotional factors, existing in the physician as well as in the patient.

to help relieve pain in common anorectal disorders

"non-caine"

Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form... both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE
OINTMENT
Soothing, Temporary Relief of Hemorrhoidal Pain, Rectal Itching
CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Acute Calculous Cholecystitis*

IT IS indeed unusual to find Staphylococcus aureus as the cause of acute calculous cholecystitis. The uncomplicated postoperative course of the patient speaks well for the therapy that was instituted, since one might ordinarily anticipate that such an organism would cause great difficulty in the subhepatic space and in the abdominal wound.

It would be of interest to know if the culture showed massive growth of coagulase-positive Staph. aureus; if not, what was the number of colonies in the culture? Was there any evidence of obstruction in the duodenum which might account for the reflux up the common duct? Lastly, it would be quite interesting to know if the histologic sections showed organisms in the wall of the gallbladder or whether they were mainly cultured from the bile and from the purulent material contained by the gallbladder? It would perhaps be important to know also if the organism could be cultured from the bile from the common duct and biliary tree.**

This has, indeed, been an interesting finding and it is important that it has been brought to our attention.

William H. ReMine, M.D.
Rochester, Minnesota

Cerebral Vasospasm

SPASM OF THE cerebral arteries has been the subject of much debate in the study of cerebrovascular accidents or strokes. It has generally been diagnosed when abrupt focal symptoms have spontaneously recovered without residual findings. It has been argued that such reversible injury to the cerebral tissue could not be caused by complete occlusion of an artery since recovery could not occur. The area would be devoid of arterial supply and in turn be severely injured and infarcted. Arteriospasm also has been alleged to persist long enough to result in permanent encephalomalacia.

For a long period, many neurologists and neuropathologists completely rejected arteriospasm as a cause of any form of stroke or cerebral injury. The transitory focal attacks were regarded as the secondary effect on the area surrounding small infarcts or hemorrhages. The neighboring regions were said to be involved by diachesis (shock) or edema, both of which are reversible. As long as the small central lesion involved only a silent area and the symptoms were secondary to the reversible neighborhood effects, recovery would be logical.

The excellent article on this subject in the January* issue of MINNESOTA MEDICINE brings out the important role cerebral angiography has played in our understanding of cerebral circulatory disease. Cerebral angiograms have demonstrated how small recurring focal cerebral episodes may result from stenosed or permanently occluded large cerebral arteries, either intracranial or cervical. The clinical picture is identical to that formerly ascribed to vasospasm. The surgical correction of the stenosed or occluded extracranial artery (carotid or vertebral) has led to recovery. This indicates an arterial insufficiency either of the main arterial supply or of the collateral circulation to the involved area. Such an insufficiency may result from any slowing of the cerebral circulation. This may be caused by an transitory drop in blood pressure. The desire to treat hypertension with too much vigor is a very common occurrence. In older people who are apt to be candidates for strokes, a mild hypertension might be superior to a normotensive state.

Brief mention should be made of the frequency of cerebral thrombosis. Over many years of examining brains in the neuropathological laboratory, the author has been impressed by the observation that a narrowed arterial lumen is more common than a thrombosis in the artery supplying the area of cerebral infarction. Perhaps in some cases the thrombosis had broken up or was dissolved by thrombolysin. These pathological observations along with angiography suggest that many cases of so-called cerebral thrombosis are actually cerebrovascular insufficiency. One case of massive encephalomalacia occurring one week after carotid artery surgery failed to reveal any vascular obstruction from the aortic arch to the brain. The site of the endarterectomy was normal. The patient was symptom-free and ready to leave the hospital. It seemed as if either transitory clotting or arterial spasm had occurred.

Strong evidence favoring arterial spasm as a cause of cerebral symptoms is seen in malignant hypertension and eclampsia. Segmental spasm of the retinal arteries of a temporary nature are seen. The article in this journal mentions the angiographic evidence for spasm in subarachnoid hemorrhage. Areas of infarction far from the site of the aneurysm appear to be caused by such spasm. The author has examined a brain showing diffuse cerebral atrophy and ventricular enlargement following repeated subarachnoid hemorrhages. Vasospasm was strongly suggested by the failure to find any pathological cause of the cerebral damage other than cerebral aneurysm. Also, a very thin layer of subarachnoid bleeding may lead to deepening coma and death. This is hard to reconcile with the mild degree of bleeding unless vasospasm is invoked. A case of pheochromocytoma* was published demonstrating segmental spasms producing a beaded appearance of the anterior and middle cerebral arteries that disappeared after removal of the adrenal tumor. I have observed one case with the same angiographic segmental appearance in the anterior cerebral artery. Following removal of the pheochromocytoma, the neurological symptoms and findings rapidly regressed.

There remains little doubt that spasms of the cerebral arteries occur and are important in certain cases and conditions. It seems likely that spasm may be associated with arteriosclerotic and occlusive vascular lesions in cerebrovascular accidents and intracerebral hemorrhages. The lesson learned from subarachnoid bleeding suggests that the degree of associated arterial spasm may be of great significance in certain cases. Even though great progress has been made, it is obvious that much research remains to be done in this field.

Mechanism and Management of Intravascular Thrombosis

THE EXISTENCE of multiple recognized forms of treatment for a clinical disease entity suggests either that there are multiple etiologies of the entity including some not yet recognized or that none of the treatment forms alone are adequate.

Thrombotic disease comes as close as any to fitting this category of diseases. An objective appraisal of the situation as put forth in the February issue by Spittell, Thompson and Owen* should be read by all physicians attempting to treat thrombotic disease states and noted especially by those adherents of the "one-treatment" technique of the surgical, drug or enzyme approach.

The surgical approaches of venous thrombectomy and ligation still have a limited application and should be resorted to infrequently. On the other hand arterial embolectomy and thrombectomy with endarterectomy are often the procedures of choice in certain arterial thrombotic disease cases.

The value of oral enzymes still so often used is to be questioned seriously. Blood levels of the enzymes in question have not been documented after ingestion of such medications. The results of this form of

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

WALLACE LABORATORIES
Cranbury, N.J.

CM-5761

treatment do not stand critical analysis when compared with those observed after other better-documented methods.

Low molecular weight dextran and lytic enzymes, while offering a hopeful future, are still experimental methods and require further evaluation before their general use can be justified.

Numerous clinical and laboratory studies of the past two decades leave little doubt of the role of tobacco smoking in the etiology or aggravation of both venous and arterial thrombosis. Abstinence from smoking should be considered a must in the treatment of all thrombotic disease conditions.

It is worth remembering that bed rest with elevation of the foot of the bed in most cases of suspected or proven deep venous thrombosis of the lower extremities is still an effective form of treatment even without the use of anticoagulants. Immobilization is conducive to stasis and progression of the thrombosis, whereas muscular activity in bed or out increases venous flow and enhances clot dissolution. For this reason, whenever possible, patients who are put at bed rest for treatment of venous thrombotic conditions should be encouraged to move about in bed as much as possible. Immobilizing hot packs and tight bed covers should be avoided if possible. The hot packs certainly provide patent comfort and aid in the early resolution of the inflammatory process. As soon as the patient is comfortable, however, such packs should be discontinued.

Superficial venous thrombosis of the extremities, except when local discomfort precludes it, is resolved more rapidly by active ambulation with elastic support than by bed rest. Prolonged sitting or standing is to be avoided. In these cases there is little or no evidence that antibiotics or anticoagulants are of benefit. Observing the precautions of determining and monitoring the white blood count at weekly intervals during treatment, resistant cases of superficial thrombophlebitis often respond to anti-inflammatory drugs such as the phenylbutazone derivatives or steroids.

At the present time, as is brought out by Spittell, Thompson and Owen, heparin is our most perfect anticoagulant and should be used acutely in conjunction with the longer acting coumadin and indanedione derivatives for long-range treatment.

Davitt A. Felder, M.D.
St. Paul, Minnesota

Hyperventilation*

Spontaneous hyperventilation is a common clinical syndrome usually on an anxiety basis. It may present in pure form or as part of a more complex psychiatric syndrome such as hysteria or depression with anxiety features. Symptoms of hyperventilation, per se, may then be interspersed with other physical symptoms due to hysteria or the many somatic complaints which frequently are associated with depression.

The syndrome of hyperventilation may occur during the day or may awaken the patient at night. The common symptoms consists of numbness and tingling of the extremities, more in the hands, often with similar symptoms affecting the tongue and mouth. This is often followed by a feeling of lightheadedness and impending syncope, with stiffness of the affected parts of the body noted above. The main complaints are usually sensory and patients may neglect to mention breathing difficulty at the onset since they may be unaware of the disturbance in breathing pattern or because the sensory symptoms are so much more striking. Other patients will volunteer that the episodes began with a choking episode of respiratory distress, usually painless; or further inquiry may elicit this information. With the choking sensation, these patients may experience

a full feeling in the throat, a form of globus hystericus. Most of the episodes tend to relent with a calm, reassuring attitude on the part of the physician and proper use of sedatives, more to quiet the resultant symptoms of anxiety and to therefore reduce the tendency to recurrence.

Because of the occurrence of throat and breathing symptoms at the onset of an attack, one must consider the possibility of tracheal or esophageal difficulty as well as chest problems such as asthma, spontaneous pneumothorax, foreign body of the trachea or esophagus, diverticulum of the esophagus or retropharyngeal abscess. The sensory symptoms suggest the possibility of tetany associated with hypocalcemia, peripheral neuropathy, Guillain-Barre* syndrome (particularly with facial involvement), polyneuritis secondary to infectious or toxic involvements of the nervous system. With the episodic nature of hyperventilation, convulsive disorder must be considered.

Voluntary hyperventilation is a standard method of activation of the electroencephalogram. In normal adult tracings the pattern is not significantly changed by three minutes of hyperventilation even though the patient may experience mild symptoms of numbness and tingling of the extremities, tongue, and mouth. Slowing is almost always seen below the age of 14 or 15 with hyperventilation, and is quite frequent between the ages of 15 to 20. After the age of 20, slowing is almost always considered to represent an abnormal response, while prior to the age of 20, the nature of the response, such as paroxysms or focal disturbances, may be of significance. It is of interest that a true petit-mal pattern is precipitated in the EEG tracing by hyperventilation and, in fact, hyperventilation in the office will usually demonstrate a clinical attack of true petit mal. It is felt that EEG slowing due to hyperventilation is a manifestation of cerebral vasoconstriction; yet it is difficult to understand why it is so unusual after the age of 20 in normal patients, when pathological studies show that beginning cerebral arteriosclerotic blood vessel changes generally occur at age 30.

When a patient with hyperventilation syndrome is examined, the increased rate and depth of respiration may or may not be apparent. Sedation is frequently effective, but the underlying pathology may not be a pure anxiety, and therefore other measures must be considered, such as psychotherapy or the concomitant use of antidepressants in depression with depression and anxiety.

In the Shadow of Isolation

OUT ON THE fringes of society exists an institution created by man from the fear of mental anguish to be suffered by others. Here is a place apart, designed to protect a patient from himself, society from the patient, and in the process, to minimize public scandal.

It is intended that these hospitals will offer protective custody, provide modern efficient treatment, serve to train future professional talent and undertake research on the vast problems surrounding mental illness. Yet there is the impression of a conflict of social purpose, containing one segment of society in the shadow of isolation. Real concern would require that these patients be given every care and attention necessary to assure their continuance in useful and contributing roles.

International data suggest that major mental disorders have relatively constant incidence. Careful cohort studies back to the turn of the century show that the percentage of recoveries is also essentially constant, the duration of illness shortened, to be sure. For more than fifty years then, we have faced the fact that the majority of patients recover from mental illness. Yet the discrimination against the mentally ill persists. If this is not so, just answer:

Where are most state hospitals located?

®

What is their size and rated bed capacity?

Where are the needed and qualified personnel?

How much is spent for total patient care?

What professional training and research goes on there?

Is there a university affiliation for teaching, training and research?

Is mental illness included in most health insurance plans?

The answers are all too clear; these facilities and patients have historically not really been part of the community. It remains then to return the problem to where it belongs — for a community problem is a community responsibility.

The establishment of facilities and the type of program should have clear goals and be based on definite needs. Unfortunately these decisions are not always reached on the basis of clearly established need, as determined by epidemiological findings. Other demands, local, personal or social, may intercede.

In many ways mental health and social problems are interrelated. Public support and professional participation could be the cornerstone to future success, a success which we know is possible and within reach. With new understanding, new purpose and community involvement, the shadows could lift. The strength of family, community, occupational and professional ties has a cohesive therapeutic and socializing effect and from this matrix could emerge a new era of community mental health, social responsibility and human welfare.

Blueprint for dealing with tension due to stress — Prolixin — once-a-day

For the patient who must be on the job mentally as well as physically, prescribe Prolixin. The prolonged tranquilizing action of as little as one or two mg. helps him cope with tension all day long. Markedly low in toxicity and virtually free from usual sedative effects, Prolixin is effective in controlling both anxiety associated with somatic disorders and anxiety due to environmental or emotional stress. Patient acceptance is good — because Prolixin is low in cost, low in dosage and low in sedative activity. Prescribe Prolixin.

Side Effects, Precautions, Contraindications: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photosensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders. **Available:** 1 mg. tablets. Bottles of 50 and 500. For full information, see Product Brief.

The Editor's Soliloquy

The 'Gimmie' Syndrome

Until 1932 this indigenous syndrome was too rare to have been recognized and described, but since that year it has become so progressively and alarmingly evident as to be distinctly noticeable in the native population.

In those who develop this insidious malady the hands are often found to be extended in supine position as if for the receiving of gratuities; and there is a coarse, centripetally oscillating tremor of the palms suggestive of a mendicant's beckoning. Though the hands are soft, smooth, and free of tyloma, frequent calluses are observed over the olecranon and the ischial tubera.

The patient's skin is sallow — with a yellowish cast over the dorsal area of the back.

The muscles appear partially atrophied, unresponsive to stimulation or command, as the patient sits in apparent catatonia from morning until night anticipating personalized attention and favor.

Because of an excellent appetite these patients usually carry an excessive deposit of subcutaneous fat. Though the blood pressure, temperature, and respiration are normal, the pulse is torpid and the bowels are sluggish — often to the point of obstipation.

Ironically, fertility is unimpaired — or even augmented.

While the intellect seems normal, the personality has deteriorated: there is no ambition, no initiative, no desire for personal achievement and independence. Incentive and drive have vanished, and moral inanition has set in.

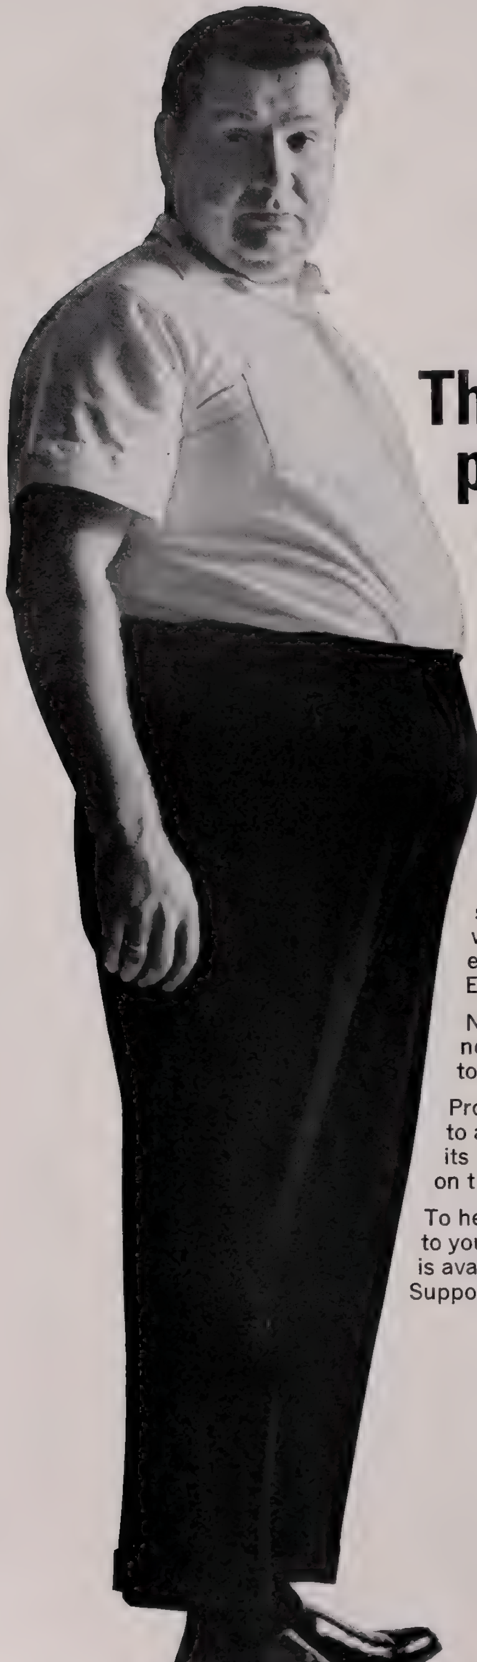
However, the apathy of these patients can be deceptive. At the slimmest prospect of extra handouts, further doles, increased compensation, or additional subsidies, a greedy glint can appear in eyes hitherto dull; necks previously inert can suddenly swivel to scan promising horizons; and lethargic bodies can galvanize into frenetic activity, utterly belying their former lassitude and immobility.

Like addicts, these sick individuals have an uncontrollable impulse to brazenly implore and shamelessly accept from society and government what they themselves would deny to others.

They have the 'gimmies.' — **Carl O. Rice, M.D.**

Mom says: If you can please a person you teach him much; if you disturb him you can teach him nothing.

Nothing has such power to broaden the mind as the ability to investigate systematically and truly all that comes under thy observation in life. — Marcus Aurelius



The population explosion

Chomp. Chomp. Chomp. He's off again on another spree of second helpings.

Tomorrow, crash! He'll be on a newfangled diet. Starving himself.

He's just one of the many who bounce between starvation and overeating, and with every rebound make losing weight more difficult.

As a professional, you can help. First by pointing out that skipping meals is no solution, and second by recommending long-range weight control through sensible eating habits and nourishing foods. Every day. Day after day.

Naturally, balanced diets and nourishing, palatable dairy foods go together; they always have.

Project Weight Watch has been initiated to assist you. Its scope is nationwide, its purpose is to focus professional attention on the problem.

To help you translate your concern to your patients, a portfolio of materials is available. Send for it. Support girth control.

disavowals of the exercise of supervision or control of Section 1801.

3. That maximum use of hospital staff authority, fiscal intermediary evaluation, and cooperative efforts should be relied upon for quality control of utilization reviews.

4. That state agency involvement in case review and survey or evaluation of active committee function be prohibited, or limited to assessment of the adequacy of 'Plans as submitted under proposed Standard Two.' "

Standard Two is the proposed outline of the structure and description of duties for utilization committees to follow.

During 1965 the American Medical Association published, circulated to all state association offices and made available to all interested physicians, hospital staffs and administrators a comprehensive handbook, "Utilization Review."

Basically designed for medical staff use, the handbook provides not only a guide to the establishment and functioning of a medical staff utilization committee, but explores the need, the philosophy, and the areas in which committees should function.

Aware of the established interests of consumers, third party payers, and government regulatory agencies in financing medical care, the handbook is built around recognition of the fact that "the medical profession should bear the majority responsibility for reviewing and policing utilization and quality controls."

The Minnesota State Medical Association remains active in utilization committee developments through attendance by the Chairman of the Committee on Medical Service, Dr. John Pewters, at the American Medical Association Medical Service Conference prior to the American Medical Association meeting, through the letter directed to presidents and secretaries of component medical societies by the Chairman of the Council, and through Council consideration and review of American Medical Association Technical Advisory Committee reports.

The situation is fluid, and changes are almost certain, through interpretation of the law, through developing regulations, and through vigorous, continuing presentation and defense of the unyielding opinion of physicians that regulatory mechanisms in medical care are medicine's responsibility, historically developed and imposed on physicians, by physicians, and always directed at improvement in patient care.

Utilization committees are now a requirement for participation in Medicare, but these actions by the Minnesota State Medical Association and the American Medical Association, prior to the passage of the Medicare Law, indicate the voluntary concern of every physician for every patient's welfare. That compulsion has now entered the picture does not modify that concern, nor should it be a source of physician alarm, as long as medicine continues to clearly identify that prior concern, as well as a continuing insistence on physician, not governmental, regulation of patient care, and of physicians' services.

Trichomoniasis

QUESTION: What has been the most valuable therapeutic management of trichomoniasis?

ANSWER: There is no question that vaginal trichomoniasis is excellently treated today by metronidozole (Flagyl). This is the first and only specific agent that has been developed. It has stood critical appraisal by a number of competent investigators. This therapy is one 250 mg. tablet three times daily for 10 days. These tablets should be taken with each of the three meals. The therapy is completed in 10 days. The husband should not be treated unless he is found to be infected and thus needs the therapy. In our experience an insignificant number of husbands were found to be contributing to the wife's infection. It is now the working rule that only the husbands of the women who have had over two outright failures by metronidozole are subjected to urological investigations. It is unwise to treat the husband without proper examination and diagnosis. He is treated only when an indication exists for it.

H. Close Hesseltine, M.D.
Dept. of Obstet. & Gynec.
University of Chicago

Enovid

QUESTION: What is the usual method of prescribing?

ANSWER: Most of our experience has centered around the use of Enovid. The drug is given in the same fashion as for ovulation control, starting on the fifth day of the cycle and being given for twenty days. In order to avoid nausea, the drug is usually given at night time. We try to give at least 0.1 mg. of mestranol. Therefore, with ordinary Enovid, if the patient tolerates the drug, we give 10 mg. per day. We have recently started using Enovid-E. It is possible that a single tablet will be effective here. Experimental data would also indicate that norinyl will be equally effective.

The Viewing Box

Systemic Scleroderma

This thirty-nine-year-old attractive Indian lady was admitted for the investigation of a dysphagia that had been progressive for several months. She complained that "solid food seemed to stick in the throat." Yet too much liquid caused her to bloat and develop a mild, crampy abdominal pain. She had been hospitalized for several days three months previously with a suspected intestinal obstruction which promptly subsided on medical management. For six months she had had a polyarthralgia, suspected of being rheumatoid arthritis. The sedimentation rate was 109. Recently she had begun to develop tingling in her fingers and toes, which often became bluish when exposed to cold. There was also some limitation of motion of the hands.

From this rather characteristic history you may already suspect the diagnosis. However, on the above G.I. series and small-bowel follow-through there are three gross roentgenographic findings which are so specific as to enable the perceptive observer to make the correct diagnosis without history (Figures 1, 2, 3). The history, however, does tell you where to look. Can you spot the significant X-ray features and give the answer?

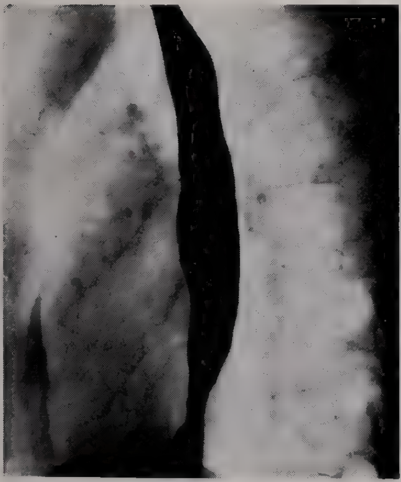

Figure 1

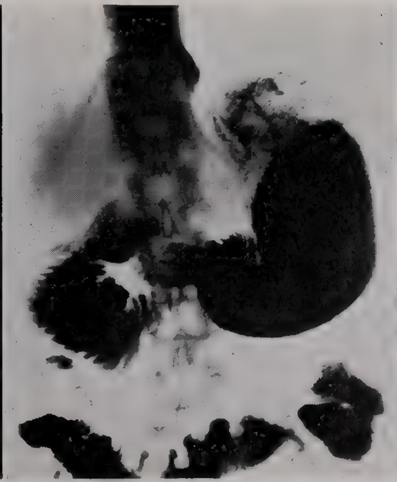

Figure 2

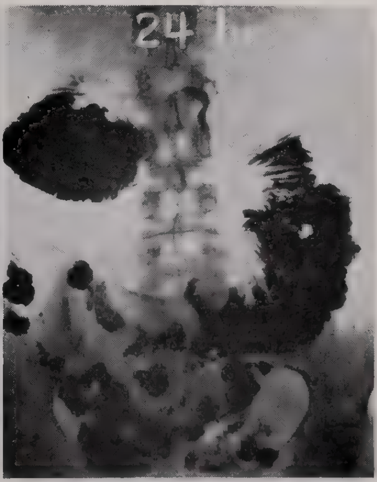

Figure 3

Continued

Editor's Note: X rays reproduced in the positive instead of the negative. Future X rays will appear in the negative.

Diagnosis: Systemic scleroderma.

The correlated roentgenographic findings here which are specific for this diagnosis are: (1) smooth constriction of the lower esophagus three or four centimeters above the diaphragm (Figures 1, 2); (2) dilated duodenal bulb and loop retaining barium for 24 hours (in spite of usual ambulant hospital activity) (Figures 2, 3); and (3) a sharp cutoff just beyond the flexure of the duodenum extending obliquely downward and slightly laterally (Figures 2, 3). This last finding is thought to be due to a pressure effect of the superior mesenteric artery on the stiffened and thickened wall of the duodenum.[5,8] Other nonspecific roentgenographic abnormalities are present in the jejunum and ileum (Figures 2, 3).

Tuffanelli and Winkelman,[11] in a study of 727 cases from the Mayo Clinic, reported that the diagnosis is about all the physician has to offer in this condition; "the etiology remains obscure; the course is unpredictable and the therapy is of little benefit." This is not a rare disease, however, as manifested by the fact that an average of 41 new patients with systemic scleroderma are seen each year at the Mayo Clinic.

The above patient had the acrosclerotic form of the disease, which is by far the commoner of the two types of systemic scleroderma. The skin changes were not striking when the diagnosis was first made. Her initial symptom was arthralgia, as was the case in 12% of the Mayo Clinic series.[11] Early in the course of the disease this symptom is often misdiagnosed as rheumatoid arthritis. The Raynaud's phenomenon and acral cutaneous sclerosis (below the mid-forearm) appear later and in that order. The acrosclerotic type favors the female over the male in a ratio of three to one. The age predilection is 20 to 50. The pathologic process frequently involves the gastrointestinal tract and other systemic organs, esophageal involvement being by far the most frequent type of gastrointestinal involvement.[4,11] Small bowel changes occur in as many as 12% of the cases of Reinhardt and Barry[8] and may be either specific or nonspecific. Occasional patients, such as ours, have presented with a picture of intestinal obstruction,[2,8] and others with a sprue-like syndrome.[3] Stomach[10,11] and colon[6,11] changes rarely have been reported. Pulmonary involvement occurs in one fourth of the cases and consists of fibrosis and sometimes cystic changes, predominantly in the lower half of the lung fields. Not infrequently cor pulmonale develops. Cutaneous calcification occurs late, on an average of 11 years after the onset of the disease[7,11] and is most frequently seen in the hands. In general the course in the acrosclerotic type is chronic.

The diffuse type of systemic scleroderma occurred in only 5.4% of the series of Tuffanelli and Winkelman.[11] In this type there is usually a central generalized cutaneous sclerosis. The extremities are spared and Raynaud's phenomenon is absent. The course is rapid and the prognosis extremely poor. The systemic manifestations are the same as those mentioned in the acrosclerotic form. Radiologic examination of the esophagus, stomach and small bowel should be performed in all cases suspected of having systemic scleroderma. Changes are not infrequently present before gastrointestinal symptoms develop.[8]

Fracture–Trauma Conference

The Elusive Malar Fracture

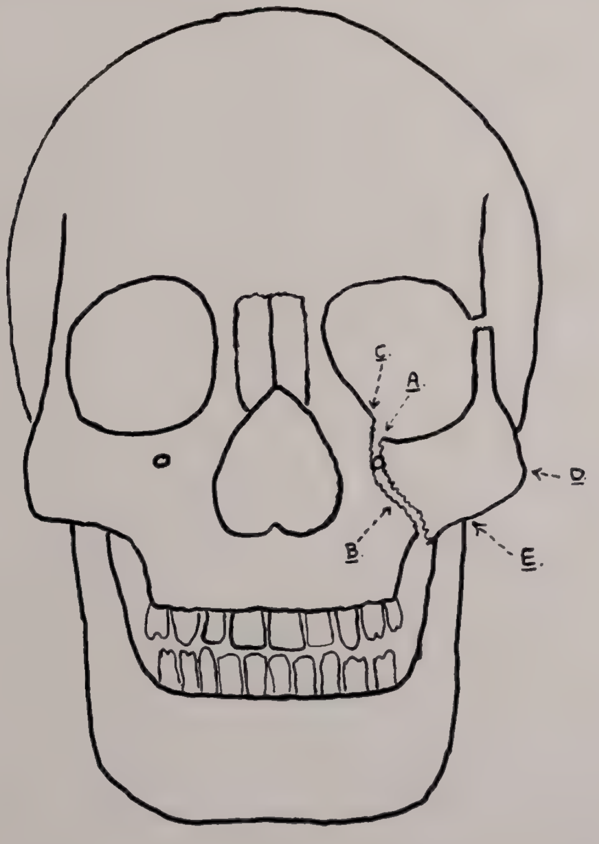
Clinical History — Accident, fell on cheek, blow over cheek

Clinical Examination — Usually considerable swelling and ecchymosis about cheeks and eyelids, "black eye." Swelling may obscure flatness of cheek prominence and notching of infraorbital ridge. Fractures may be difficult to visualize on "skull films."

Specific Inquiry to Suspect Zygoma Fracture

Fractures usually occur at thinnest and weakest portion of bone.

A. Numbness infraorbital nerve distribution — injury in fracture site.



Continued

B. Unilateral epistaxis — lateral antral wall involved.

C. Diplopia — may have "double vision" if inferior oblique or inferior rectus involved in fracture site.

D. Flatness over cheek prominence — due to inward depression of bone. Better appreciated by viewing cheeks tangentially from above forehead. Swelling over cheek often obscures flatness and delays complete appreciation of underlying depressed fracture.

E. Restriction of lower jaw motion. Inward depression of arch portion of zygoma reduces space between mandibular coronoid process and zygoma, producing a "tightness" or "binding" on lower jaw movement.

Roentgenographic Exam to Confirm Presence of Fracture

Water's view (chin on plate) best. Fracture line along infraorbital ridge. Clouding (blood) antrum on involved side. Body and arch depressed inward (may be best seen on vertico-submental view).

Operative Reduction of Depressed Zygoma Fracture

Outward and upward traction by grasping forceps inserted into bone through cheek skin.

Elevation of zygoma by instruments inserted under portions of bone.

Open surgical exposure of fracture sites with wiring may be required to maintain corrected position.

Early diagnosis helpful to allow operative reduction in first few days if possible. Reduction of bone to original position more difficult and less satisfactory as time elapses.

Lyle V. Kragh, M.D.
Minneapolis, Minnesota

(See Acute Calculous Cholecystitis, page 439.)

Did the culture show massive growth of coagulase positive Staph. aureus?

Yes, it did, and no other organism was grown.

Was there any evidence of duodenal obstruction?

No. Neither at surgery nor pre or post-operatively.

Did the histological sections of the gallbladder show organisms in the wall, was the culture mainly from the bile and purulent material in the gallbladder, was the organism cultured from the bile of the common duct and biliary tree?

The histological sections of the wall of the gallbladder showed multiple micro-abcesses scattered throughout which were packed with PMNs. Only the content of the gallbladder was cultured; the remainder of the biliary tree was not opened.

Tumor Conference

Cystosarcoma Phyllodes

A 39-year-old married white female was admitted for an elective excision of a 3-cm. firm, nontender, somewhat lobular and nonfixed mass of the left breast of three months duration. Frozen section was suspicious of malignant cystosarcoma phyllodes, and paraffin sections were awaited before determination of definitive surgery. The tumor was considered malignant. Outside pathological consultation advised radical mastectomy because of the highly disturbing epithelial components. The radical breast operation was done; the specimen showed no residual tumor, and all of the lymph nodes were negative.

Without the disturbing histologic findings suggesting malignancy, a simple mastectomy would have been the operation of choice. The malignant changes in the epithelium are not sufficient to classify this case as a carcinoma. The combination of carcinoma and cystosarcoma phyllodes within the same tumor has been reported in only one case.[1]

Comments

Cystosarcoma phyllodes is an uncommon fibroepithelial tumor of the female breast. As the clinical behavior does not always follow the histological pattern,[2] Treves[3] aptly described this lesion as the Dr. Jekyl and Mr. Hyde of the breast. Over 43 different terms have been ascribed.[4] Much confusion has arisen in the literature in regard to the microscopic classification and related surgical treatment. This frustration is due in part to the inability of pathologists and surgeons to gain a wide clinical experience with this neoplasm. Furthermore, the term cystosarcoma phyllodes, originally applied by Johannes Mueller and Chelius[5] to a benign tumor, has remained as a descriptive term for a neoplasm which is either benign or malignant. Some authors,[6] however, state that this lesion is not malignant but simply a fibroadenoma with sarcoma-like stroma. A recent report by Oberman[7] has helped to clarify this subject. He would prefer to designate those neoplasms with benign stoma as "cellular adenofibroma" and those with malignant stroma as "periductal fibrosarcoma." Yet the term remains and thus the confusion continues.

According to Oberman,[7] it is now generally accepted that cystosarcoma phyllodes is a fibroepithelial tumor characterized by an increased cellularity of the mesenchymal stroma. This does not inclue mesenchymal lesions of the breast that have no epithelial component. It is unfortunate that the qualifying terms 'benign' and 'malignant' have been added; between these, Treves and Sunderland[8] have placed a "borderline" group in which the

Continued

pathologist cannot categorically state whether the tumors are microscopically benign or malignant.

The lesion may occur from adolescence[9] to old age, with the average age around 50. Bilateral occurrence is rare.[2,3,10] Grossly, the lesion may rapidly attain massive size and weigh several pounds,[5] but a small tumor does not rule out cystosarcoma phyllodes. In 93 cases reported by Treves,[3] 29 were 2 cm. or less and one case of 1 cm. size was malignant. Oberman[7] has also emphasized this feature. With rapid growth or massive size, skin ulceration and avascular necrosis may occur. Necrosis and ulceration do not signify malignancy but only loss of blood supply.[3] With malignant tumors, growth may extend into the pectoral muscles, ribs and pleura.[7,8] Metastasis is by the blood stream.[3,7,8] Lymph-node metastasis was reported in one case by Treves.[3] Cooper and Ackerman[11] also reported a case with lymph-node metastasis; however, no mention of an epithelial component within the breast tumor is made. When metastasis occurs, progression is usually rapid.[3] The metastatic lesions are composed of sarcomatous stroma with no epithelial component.[2,3,7,8]

Gross Appearance

Grossly,[2,4] the tumor is greyish white, fleshy and mucoid; it appears encapsulated, and its cut surface tends to "bulge" out. Cyst-like spaces may be present.[2,3,5] With large tumors, distended veins[3,4] are often seen covering the affected area of the breast.

Histologic Appearance

Microscopically, benign cystosarcoma phyllodes has hyperplastic stroma without atypism.[7] Hypercellularity may be more prominent near the epithelial elements.[7] The ducts may be elongated and compressed. Papillary infolding of the epithelium can occur along with intraductal epithelial proliferation. Orderly mitoses and multinucleated giant cells are common. Oberman[7] stresses this feature and emphasizes that such findings do not indicate malignancy; in nine benign cases,[7] orderly mitosis near the ducts was found. Zones of cartilaginous and osteoid metaplasia have been reported.[2]

Microscopically, malignant cystosarcoma has marked focal cellularity and severe nuclear atypism, with atypical mitotic activity.[7] This atypism and activity are removed from the periductal areas and may be found at the periphery of the tumor or in the adjacent fat.[7] The sarcomatous areas may be only focal in nature and consequently easily overlooked.[2,3,7,8] Thus, much emphasis has been directed to the absolute necessity of obtaining multiple samples before a lesion has been labelled benign. This feature, in the past, has led to inadequate surgical removal.

Between the benign and malignant group Treves[3] has placed a borderline classification in which there is a mild atypism of the stromal cells. Oberman[7] prefers the term low-grade malignancy.

The incidence of malignancy cannot be accurately assessed unless the authors have made adequate sampling of the tumor. Following this standard, Treves[3] has reported 15 malignant lesions in 93 cases (16.6%), Oberman[7] seven in 18 cases (38.9%), and Lester and Stout[2] 20 in 56 cases (34.4%). In spite of adequate sampling of the tumor, final analysis may not be possible unless the lesions have recurred with a histologically malignant picture or have metastasized.

Treatment

Surgical treatment[1,2,3,4,7,12] requires wide and complete removal of the neoplasm. In order to prevent local recurrence, benign lesions should be removed widely, not merely by biopsy excisions. Large benign neoplasms may thus require simple mastectomy. Malignant lesions are best treated by mastectomy with removal of the pectoral fascia and pectoral muscles if necessary.[7] Extension of the tumor may necessitate removal of a portion of the chest wall. Borderline or "low-grade" neoplasms should be treated by simple mastectomy unless a small lesion can be "widely" excised. Metastasis occurs via the blood stream and thus radical mastectomy is not deemed necessary.[7]

It is essential that a careful follow-up of these patients be made.

Deaths from cystosarcoma phyllodes are uncommon. Mortality rates in malignant cases cannot be accurately ascertained because of the confusion in reporting. Where careful studies have been reported, it would appear that an 18% figure would be close:

	Malignant Cases	Deaths	%
Treves[3]	15	1	
Lester & Stout[2]	21	3	
Oberman[7]	7	4	
	43	8	18.7

Summary

A case of malignant cystosarcoma is reported in which a radical mastectomy was performed because of the highly disturbing epithelial components.

Cystosarcoma phyllodes is an uncommon fibroepithelial tumor of the breast which requires thorough pathological sampling. Classification may be difficult. The clinical course does not always follow its histological appearance and thus careful follow-up of the patient is essential.

Regardless of the microscopic picture, wide excision should be done. Metastasis occurs via the blood stream, and in these cases progression is usually rapid.

Because Johannes Mueller used the term cystosarcoma phyllodes, its classification has since caused a great deal of confusion.

Anorectal Surgery

Is Urinary Retention a Necessary Complication of Anorectal Surgery?

Urinary retention following surgical procedures on the anal canal and lower rectum occurs in thirty to forty percent of patients in most reported series. When urinary retention occurs, the bladder must be catheterized from one to three times, and in some patients it becomes necessary to insert a Foley type of indwelling catheter. Far too often the insertion of a bladder catheter is followed by urethritis and cystitis with the usual symptoms of frequency, burning, lower abdominal discomfort and fever. Chemotherapeutic and antibiotic treatments of urethral and bladder infections are expensive, not always efficacious, and at times lead to further complications.

The accepted cause of urinary retention following surgery on the anorectal region has been the theory of spasm due to the phenomenon of reflex pain. Since the bladder, urethra and supporting structures of the pelvic urinary system are innervated by the visceral branches of the second, third, and fourth sacral nerves through the pelvic plexus and since the branches of the same nerves via the pudic, inferior hemorrhoidal and dorsal nerve of the penis innervate the anal area and distal portions of the urethra, it has been reasonable to assume that reflex pain, spasm and inability to urinate would necessarily occur in a large number of patients.

Encouraged and stimulated to reject this theory by Dr. Richard A. Hopping of East Orange, New Jersey, whose experience on a large number of patients convinced him that the cause of urinary retention was to be found in a different theory, the author adopted Dr. Hopping's postoperative routine for anorectal surgical patients. One hundred and twenty-five consecutive patients were operated upon for the usual anorectal surgical conditions, and a bladder catheter for immediate postoperative urinary retention was used in only one case. This patient was a highly nervous and tense individual who was unable to cooperate.

The newly adopted routine consists of limiting intravenous fluids during the period of anesthesia to less than 200 cc. On the day of surgery the orders call for nothing by mouth except occasional sips of water. Early on the morning of the first postoperative day the patient is placed in a shower or tub bath and encouraged to void. The results have been uniformly successful.

In the light of our present experience it is logical to assume that urinary retention following anorectal surgery is due to bladder distention, or overdistention, in the immediate postoperative period and not due to reflex pain and spasm.

One hundred and twenty-four out of one hundred and twenty-five patients successfully emptied their bladders within twenty-four hours after undergoing anorectal surgery using the newly instituted postoperative routine.

Butazolidin® alka

phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

Usually works within 3 to 4 days in osteoarthritis

The trial period need not exceed 1 week. In contrast, the recommended trial period for indomethacin is *at least 1 month.*

That's why it's logical to start therapy with Butazolidin alka—you'll know quickly whether or not it works. And usually, it will.

A large number of investigators have reported major improvement in about 75% of cases. Some patients have gone into remission. Relief of stiffness and pain may be followed quickly by improved function and resolution of other signs of inflammation. And Butazolidin alka is well tolerated, especially since it contains antacids and an antispasmodic to minimize gastric upset.

Contraindications
Edema, danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile, or when other potent drugs are given concurrently. Large doses are contraindicated in patients with glaucoma.

Precautions
Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Make regular blood counts. Use greater care in the elderly.

Warning
If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy.

Adverse Reactions
The most common are nausea, edema and drug rash. Hemodilution may cause moderate fall in red cell count. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Dosage
The initial daily dosage in adults is 300-600 mg. daily in divided doses. In most instances, 400 mg. daily is sufficient. When improvement occurs, dosage should be decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

Also available: Butazolidin®,
brand of phenylbutazone
Tablets of 100 mg.

Neuro-Pediatrics Conference

Retarded Speech*

Focal or Diffuse Cerebral Disease?

Dr. Edward Defoe**

This six-year-old boy was first seen at the University of Minnesota Hospitals August 7, 1962, for evaluation of developmental retardation, seizure activity and right hemiplegia.

Delivery was reported to have been uneventful following a full-term pregnancy and uncomplicated labor. Birth weight was 7 lbs., 11 oz. No significant neonatal illnesses were noted. Although neuromotor milestones are somewhat vague, the patient was said to have been somewhat slower than his sibs. He walked at 18 months and was neither toilet trained nor talking at three years when first seen at the University Hospitals. At 15 months he fell from his crib, striking his head; but this was not considered a serious fall. He had no loss of consciousness and no apparent complications, and he was not seen by a physician. The first generalized seizure occurred at 18 months. Seizure activity continued (mainly 15 to 20 minutes after going to sleep) in spite of Dilantin suspension (100 mg. per 4 cc.) ½ tspn. three times a day. At the time of the first University Hospital visit, the parents noted his irritability, clumsy gait, poor control of his right arm and leg, and some difficulty swallowing solid foods.

Physical Findings

Physical examination on August 7, 1962, accomplished with great difficulty because of the patient's apprehension, revealed an obviously retarded child with no speech, a grossly ataxic gait and a right hemiplegia. His head circumference was 49 cm. and his weight and height were just below the 15 percentile.

---

*Held on Wednesday, October 6, 1965 at 1 p.m. in Hibbing, Minnesota.

Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held weekly from 1 to 2 p.m. every Wednesday. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Edward C. Defoe and Dr. Charles Branthaver in Pediatrics and Dr. Robert Soll in Adult Neurology.

**Pediatrician, University of Minnesota Hospitals, Conference Moderator.

Continued

Progress

An electroencephalogram revealed a spike focus in the left frontal area. Carotid angiography demonstrated right and posterior displacement of the left anterior cerebral artery. The left frontal lobe appeared quite avascular.

A left craniotomy was done for a suspected tumor. None was found. The brain in the left frontal area was quite firm with large overlying cortical veins and subarachnoid adhesions. The pathological diagnosis was diffuse gliosis with no evidence of neoplasia.

Following discharge on phenobarbital ½ gr. three times daily, he was seen again March 11, 1963. No further seizures were reported and he appeared to be using his right arm more. Head circumference was still 49 cm.

He was again seen August 10, 1965, because of parental concern over his retarded speech. At this time he was reported to have seizures occurring at approximately two-week intervals, with anticonvulsant therapy consisting only of elixir of phenobarbital (20 mg. tspn. twice daily). Most seizure activity had occurred approximately 15 to 20 minutes after he went to sleep. Although he is now toilet trained, he is unable to dress himself; he is able to speak only two or three words, preferring to point to objects. He continues to be apprehensive with strangers and covers his eyes when disturbed by loud noises or when confronted by strangers. Physical examination again revealed a frightened, retarded child with moderate spasticity of the right arm and leg. His weight and height were slightly below the 15th percentile. Head circumference was 49.5 cm. No speech was demonstrated.

Hemoglobin was 10.8 gm. The red cells were slightly hypochromic and microcytic.

Dr. B. French*

I did not see this boy until he was two years of age. He was noted to have a "flat head" at four months of age, and there is a note that "he should be watched closely." At 13 months a question of developmental retardation was raised by the pediatrician. However, no definite neurologic deficit was detected on physical examination. The diagnosis was "grand-mal epilepsy," which was treated with Dilantin ½ teaspoon three times daily. At the time of my last examination of him in January, 1962, he had poor coordination of the right arm and leg with a suggestion of ataxia, and I was suspicious of a lesion in the left hemisphere.

Dr. Michael Blaw**

In evaluating seizure patients one of our concerns is whether the seizures are a manifestation of an expanding intracranial mass and consequently whether contrast studies are indicated. Briefly stated the criteria used are: (1) Signs or symptoms of increased intracranial pressure; (2) Signs or symptoms of progressive neurological deficit, including behavioral, intellectual and seizure pattern; (3) Progressive slow-wave changes in the EEG.

Superimposed on the history of a boy with many stigmata of neurological deficits dating from birth was the story of the onset of a convulsive disorder. This symptom in itself might not warrant contrast studies if it were not for the history of progressive hemiparesis of recent onset. The pneumoencephalograms reveal that the anterior pole of the left ventricle is "cut off." The carotid angiogram shows avascularity in the area of the left frontal lobe. Both of these findings are consistent with a space-occupying neoplasm; hence, expectations were high that craniotomy would reveal a tumor. However, no tumor was found at the time of exploration.

---

*Family physician.

**Pediatric neurologist, University of Minnesota Hospitals.

Dr. Defoe

Dr. Blaw, do you believe that these changes could have been secondary to the fall recorded at 15 months?

Dr. Blaw

No, I don't believe the two are related. The primary problem is most likely a cerebral anomaly unrelated to trauma. Of great significance is this boy's lack of speech. Speech development is usually centered in the left cerebral hemisphere. Although a left hemisphere lesion in a seven-year-old may produce aphasia, the entire left hemisphere may be removed prior to age three and still allow normal speech development. Speech function, therefore, is transferred to the right hemisphere under these circumstances. In this child the presence of poor speech development before the age of three would indicate either bilateral lesions or very diffuse brain involvement. He does indeed have indications of discrete involvement of his left hemisphere as manifested by his hemiparesis, but he also has evidence of diffuse involvement as suggested by his small head and intellectual deficit.

Dr. Defoe

Dr. Blaw, although this child's seizure problem temporarily abated after the initial hospitalization, the seizures are now severe, occurring every two weeks, and are of great concern to the parents. What recommendations do you have for medication?

Dr. Blaw

I note he has been on elixir of phenobarbital in rather small doses. I would suggest tablets be used instead. These can be crushed and given in a sweet vehicle of one kind or another. I would further suggest a phenobarbital dosage of 3-5 mg./kg. per day and dilantin 5-8 mg./kg. per day. Phenobarbital 15 mg. in the early morning, 15 mg. in the early afternoon, and 30 mg. one hour before bedtime in addition to dilantin 50 mg. in early morning and 50 mg. before bedtime would be a logical start. It will be extremely important for the mother to understand why these doses are necessary at the times prescribed, the importance of no omissions, and the importance of close contact with Dr. French for further dosage adjustment.

Dr. Harold Ireton*

I would ask whether this child's language problem represents a relatively specific aphasic disturbance or is but one reflection of more general mental retardation.

---

*Psychologist, University of Minnesota Hospitals.

Continued

To communicate, he relies heavily on pointing or making facial gestures. His mother reports that this procedure is very effective at home ("there isn't a thing I don't know he wants," she says). He makes quick use of his mother whenever he is frustrated, and it is likely that she tries her best to help him at all times.

Intelligence and related testing was undertaken to document the generality and degree of retardation in areas other than language function which was his parents' specific focus of attention. On a battery of tests the boy failed to demonstrate functioning in any area beyond a four-year-old level. (He was six when tested.) On tasks requiring visual motor coordination, his performance was poorest (at about a three-year-old level).

His performance on cognitive tasks not requiring a verbal response and his rated social maturity would suggest an IQ of about 60, which places him within the educable range. However, such a "straightforward" classification is seriously compromised by his markedly inferior language skills.

The present evaluation indicates significant general mental retardation beyond impaired language skills. Further, his performance suggests that when he has to produce in a complex, coordinated fashion, as in the Goodenough, he is particularly deficient. Expressive language also depends on the ability to undertake complex coordinated activity in the production of speech.

Miss Helen Kretchmer*

The father is 16 years older than the mother. He has had 33 years of steady employment with the railroad. Both parents seem relaxed with the other children. Their main worries over the boy revolve around his seizures, his lack of speech, and his school placement. One or the other of them sits with him for an hour or so after he goes to bed, because this is the time he commonly has convulsions. Incidentally, he sleeps with his ten-year-old sister. This is also a precaution taken for early recognition of the seizures. This fear of seizure activity has undoubtedly been a major contribution to the mother's over-protectiveness of the child and certainly will add to her apprehension over letting him leave for a school setting. Although both parents are concerned over his lack of speech, the mother has probably done little to foster independence. Their understanding of the limitations and potential is probably not currently realistic and they will need continued gentle understanding support and guidance.

As a family, they go out very little. The parents are fairly well isolated at home with the patient. There are no relatives nearby. In addition to general medical advice and speech and school help for the boy, the mother also needs advice in daily living and instruction as to how the patient can be educated to help himself more.

Dr. W. F. Hunter**

It might be wise, in the area of self-help, to enlist the aid of Miss McCarthy who is a physical therapist here at the Hibbing Hospital. She undoubtedly could be most useful in setting up patterns for the mother to follow.

---

*Social worker, University of Minnesota Hospitals.

**Director, Range Mental Health Center, Hibbing, Minnesota.

Mrs. Judy Edmonds*

My initial speech, language and hearing evaluation was done on August 20, 1965. The boy is a rather hyperactive child and difficult to evaluate. His attention span is short, he is distractible, and it was difficult (but not impossible) to involve him in various tasks. Physically he is rather awkward. He used his left hand almost exclusively. He even operated a wastebasket foot lever with his left foot; he showed poor balance when asked to use his right foot.

The mother was extremely protective during the evaluation — jumping to pick up blocks he had dropped, helping him with puzzle pieces, and groaning when he made errors on language test items. She admitted waiting on him hand and foot at home, a fact which is probably partly responsible for his lack of social and self-help skills. (It was interesting that when I took him to the restroom he stood and waited for me to take his pants down or pull them up. When I suggested that he do it himself, he did so.)

Movements of his arms were occasionally jerky when he was asked to point to various parts of his body; but I was not sure whether this was due more to lack of physical control or to lack of certainty as to what he was to do.

Speech and Language Behavior

Receptive

His understanding of language was commensurate with his mental age. He followed directions involving prepositions "on," "under," and "over," but not "around." He knew most body parts but missed "foot" and pointed to his feet only when they were named. His response was not always immediate, which could have been due either to lack of understanding or to lack of cooperation. No formal test of hearing was made but as he followed directions given at a whisper without any visual cues, hearing acuity for speech sounds was adequate.

Expressive

He manipulated his environment and met his needs almost entirely by gesture. For example, he pulled at himself to show that he needed to "potty," pointed at things he wanted, etc. Usually gestures were not accompanied by any kind of verbalization. There was an occasional "uh" or "du" but not much more. He used the word "ball" several times, also "mom," "no," and "uh-oh." With those exceptions there was no vocalization. (He did make sounds for a pistol.)

The mother reported that she hears very little vocalizing at home, except an occasional "uh" when he needs to get her attention.

He was not persuaded to try any other words or any other sounds during this evaluation. His usual response was to go to his mother and whisper "du" in her ear. (Later he did this with me.) This was never vocalized and was nearly always the same consonant — "d." When we tried the "sh" sound, he puckered his lips but made no sound. His mother says he often uses this whispering in her ear at home. She thinks he is learning "good night" and "goodbye." The parents have not put much pressure on him to talk, but they think he is doing more vocalizing now than before. He has never done much babbling.

He copied two taps and three taps.

Peabody Picture Vocabulary Tests

He scored 37 (inconsistent pattern of errors) with a vocabulary age 3.7.

Motor Encoding Subtest of I.T.P.A.

His score was eight, which is at language age level 3.6.

Visual Motor

He had difficulty fitting simple puzzles together, did not copy block patterns of any sort, drew straight lines and circles at the third-year level of development, but did not copy the cross or the square.

Draw-a-Man (Goodenough)

This was essentially scribbling. His mother says he has not had much experience at home drawing or coloring. He plays outside most of the time. She says she thinks he can do better on drawing a man. Typically (at home) he draws a circle with eyes and nose and one ear. The other ear is elsewhere on the page.

Speech Mechanism

He controlled his tongue movements fairly well. Touch localization sensitivity of the tongue and lips was fairly good. He would not try to imitate any speech sounds; ability to do this should be further evaluated.

Auditory Discrimination of Noise Makers

Discrimination performance was inadequate but he may not have understood the task involved.

A further effort was made to evaluate his ability to produce speech sounds. With M & M reinforcers, he was persuaded to try and was able to produce vowels uh, oh, a, ah, and consonants b, p, t, l, m, and sh (without fricative components). He did not succeed in producing e, a, i, oo, or u. He imitated some pitch variation. He did much more vocalizing of vowel sounds this time than when last seen.

Summary

There are obviously many complex factors involved in this boy's lack of verbal communication. Partial motor apraxia and word aphasia are strong possibilities. Not to be ignored, however, is some lack of motivation to learn speech — imposed upon this boy's other problems. His hearing is adequate and his understanding vocabulary is commensurate with his IQ age. There appears to be nothing wrong with his speech mechanism. However, his expressive vocabulary is quite limited. There is little stimulation at home for learning speech. If he could have specific therapy (for example, the McGinnis "Association Method" would be appropriate) outside of the home for one-half hour daily, this would determine better the extent to which he can acquire an expressive vocabulary. A large amount of "reinforcement" for efforts will be important to the success of this type of training. Along with this, the mother can receive instruction in an approach which will promote acquisition of a receptive vocabulary to the maximum extent possible.

Concern was generally expressed that the boy is not ready for a regular school kindergarten environment because of his social, speech and general development limitations. Yet he badly needs stimulation from peer integration and a broader group experience for social reassurance. The best course for initiating his social debut in a manner least anxiety-provoking for the boy and his parents might be participation in a four-hour-a-day nursing school; or attendance in the Day Care Center in Chisholm would be a good alternative. Ultimate participation in special classes within the school system will necessarily depend upon progress noted within a more sheltered environment.

Dr. Defoe

This is a developmentally retarded boy who is functioning intellectually in the low educable range but who is further handicapped by lack of speech development, a hemiparesis, seizure activity and a continuing over-protective home environment. Better control of the seizures (through medication adjustment) will also come through social involvement in a protected nursery school or day care center and through specific speech instruction by Mr. R. Larsen.* More accurate judgement of the boy's ultimate potential for speech development and ultimate school placement must await such a trial period. Dr. B. French will continue to function as the primary physician responsible for medical management of the child and for continued guidance and support to the parents. University professionals will be available for further consultation when this is deemed appropriate by Dr. French and school personnel.

Addendum

Dr. Ward Darley has said (1) "*Medical Care*—concerns the functioning of our total medical establishment; all of its personnel and facilities and all organizational methods for the administration and financing of services; (2) *Patient Care* — while a part of medical care is the exchange and the results of the exchange that takes place at the level of the individual patient with his physician; (3) *Comprehensive Care* — is a system of person- and family-centered service rendered by a well balanced, well organized corps of professional, sub-professional and technical personnel who, by using facilities and equipment that are physically and functionally related can deliver effective service at a cost that is economically compatible with individual, family, community and national resources."

It is evident comprehensive care must encompass care which is optimally effective on a long-term basis, which means that one physician must have the primary responsibility for ongoing patient care. Yet there is a tendency in modern society to supplant this with episodic fragmented professional responsibility. Principal factors encouraging this relate to: (1) an increasing trend toward specialization, (2) increasing population movement, (3) the emergence of complex chronic disease which knows no clear-cut end point, and (4) increasing expectations of society for maintenance of health.

Dr. Lester Evans has stated in reference to comprehensive continuing care:[2] "There is nothing new or complicated in the concept. Basically, comprehensive medical care is the kind of compassionate personalized

Continued

birth-to-death attention — preventive, advisory and rehabilitative as well as diagnostic and therapeutic — that the ideal family physician used to give (and sometimes still gives) within the limits of his knowledge and facilities.

What is new and complicated is adapting the concept to the uses of urban society and specialized skills; so that medical care does not become increasingly an episodic, impersonal and even haphazard matter of a patient's shopping in bewilderment from specialist to specialist, none of whom may know the emotional and environmental problems interacting with his organic complaint. The aim should be to combine the concentrated knowledge and skills of the specialists with the broad understanding, wisdom and continuing care of the generalist to the end that the patient receives precisely as little or as much care as he requires."

The principal aim of conferences such as this one held in Hibbing is encouragement within the community for the development of a true comprehensive approach to complex chronic problems. This approach must recognize the importance of close cooperative community effort, as well as effective utilization of other consultative sources, with retention of primary physician responsibility which promotes continuity of interest and involvement with the patient on a long-term basis.

Edward C. Defoe, M.D.
Conference Moderator

Those Participating in the Conference

Dr. B. French (family physician), Dr. W. Hunter (Director, Range Mental Health Center), Mr. R. Larsen (speech therapist, Hibbing Independent School District #701), Mr. Parker (Superintendent of Schools, Hibbing), S. Weinberger (Jefferson Elementary School, Hibbing), L. Seppi (special class teacher, Buhl), E. Stubblebire (Field Nurse State CCS for N. E. Minnesota) and other professionals from Hibbing and the surrounding communities. Mr. Blaw (pediatric neurologist), E. Defoe (pediatrician), J. Edmonds (speech therapist), H. Ireton (psychologist), and H. Kretchmer (social worker) from the University of Minnesota Hospitals.

REITER'S SYNDROME*

Arthritis usually dominates the clinical picture of this syndrome with nonspecific urethritis, and conjunctivitis. There is acute pain, tenderness, swelling, heat, and effusion occurring in the weight bearing joints. This may be preceded by urethritis and conjunctivitis. The urethritis usually subsides within four weeks and the conjunctivitis continues for about ten days. There may be peripheral lymph adenopathy and cutaneous lesions resembling erythema multiforme. A viral etiology is suspected but no causative organism has been regularly demonstrated. The eventual prognosis is good and recovery is complete with ACTH cortisone producing dramatic results.

Child Psychiatry

Behavior Problems and Cerebral Dysfunction in Children[*]

Part II

Diagnosis

Most physicians, well trained in a medical setting but lacking in training which only experience can provide, may feel insecure and yearn for an objective, structured approach when confronted with the responsibility for diagnosing and evaluating a perplexing behavior problem. The "whole child approach," so-called, is such a technique. It suggests one cannot consider a child's behavior as an entity in itself. It must be considered in the light of his physical health, his psyche, his emotional environment at home, school, etc. In brief, the physician's investigation should include:

1. The standard pediatric examination
2. Evaluation of the emotional status of the child and his environmental setting.
3. A functional neurological examination which concerns itself specifically with:
    a. neuromuscular function
    b. sensory function
    c. the sensorium
    d. possible history of impulse behavior
    e. intellect
    f. perception

The Standard Pediatric Examination

A considerable number of physical diseases in children present behavioral symptoms. An examination by a physician with pediatric diagnostic acumen is an essential part of the study of a behavior problem. For obvious reasons the practice of child guidance without benefit of a previous pediatric examination in the diagnostic study cannot be condoned. It must be an essential part of the total study.

Evaluation of the Emotional Status of the Child and His Environment

Medical practice provides us with a number of effective tools for this type of appraisal. Some of them are: the child's and family's cumulative observations concerning attitudes and feelings of the patient and members of the family toward each other and toward his staff during the periods of stress associated with disease. The attitudes and reactions of the child and individual family members toward the study of the "behavior problem" are likewise important. The failure of the father to concern himself about his child's predicament may be a significant indication of his attitude toward the situation.

Clearly, to use such tools effectively in the diagnosis and treatment in the area of feelings and attitudes, requires skills to observe, interview and communicate meaningfully with not only the patient and his parents, but

---

[*] See Minnesota Med 49:305, 1966 for Part I.

Continued

also teachers, pastors, camp leaders and others who may be important in the child's environment. Such skills are not inherent in a physician; they have to be learned and developed. Unfortunately, formal training to observe, interview and communicate is not developed to any degree in the physician's and pediatrician's education. To acquire such skills requires initiative on the part of every individual physician. He must acquire the skills in question to deal effectively with the problem of the misunderstood child.

The Neuromuscular Examination

Observation of the child in active play is the most discerning test for revealing subtle neuromuscular functional deficiencies. In the office, it is excellent practice to observe how the child handles himself in play and ordinary activities. Such observations can be made in the waiting room or in the office, noting how the child plays or how he climbs on and off the examining table. He can be asked to skip and hop and to do several things at one time, such as extend the arms while closing the eyes and turning the head. In my own experience, except in the event of hyperactive knee jerks in the prone position and/or the inability to slide the heel of one foot down the shin of the other leg, the orthodox neurological examination has not been as useful as observing the child in action.

A comparative evaluation by an experienced, observing kindergarten teacher may be more helpful than a referral to a neurologist. The report of the former might read (as indeed one report did), "He has not yet learned to work or play with others satisfactorily. He is not cooperative or dependable with such things as putting on his clothes. Such skills as cutting and skipping are not yet mastered. His work habits are unsatisfactory, his drawing is little better than a scribble. He is interested in numbers and recognizes many." No committment was offered that a neurological deficit might explain such behavior.

Parent observations regarding neuromuscular function are prone to be unreliable.

Sensory Examination

The evaluation of sensory function is limited for all practical purposes to hearing and vision. An audiogram and Snellen test have been useful routines. An ophthalmological consultation is indicated if there is a question regarding vision, even in the presence of a normal Snellen. It is most damaging to the physician's rapport with a family when, later, a visual or hearing handicap that should have been revealed by the initial examination is noted. Thoroughness should be the watchword.

Sensorium Examination

Defects in the sensorium cause variation in the state of consciousness. Abnormal electroencephalogram tracings are seen in many children with brain injury but are also recorded in a significant proportion of "normal" children. An occasional child with unrecognized petit-mal epilepsy may be diagnosed by means of pathognomic encephalogram tracings; otherwise, in clinical practice it creates more problems than it solves. Based on my own experience I request an electroencephalogram only in a case of suspected petit-mal epilepsy. In three of my patients with previously unsuspected petit-mal, the clinical history on each case was most suggestive of the disorder.

Impulse Control

In the process of the child's maturation, an essential ingredient to satisfactory living is the development of impulse control. Fortunately most children learn this relatively early. Many children, however, with unrecognized cerebral dysfunction have difficulty mastering impulse control because of an inability to inhibit or delay response to environmental stimuli. They tend to have a short attention span, are easily distracted, engage in successive activities — often without completing a task, and tend to have difficulty when involved with large groups. Being unable to control their impulses, they are frequently in trouble in the classroom, playground and school bus. They lack the capacity to keep friends. It can be said they tend to do nothing in particular but what they do is done erratically.

In my experience this group of children lacking impulse control due to cerebral dysfunction demonstrated definite signs and symptoms of incoordination and distortions in perception.

One must always keep in mind the possibility that emotional tension due to excessive environmental stress may produce a similar lack of impulse control in other children.

Intellect and Perception

A clinical psychological consultation is desirable and often essential in evaluating intellectual, perceptual and academic achievement. It may also provide information regarding the emotional status of the patient. A good working relationship with his psychological consultant is essential for the physician. He must also be familiar with the various psychological tests in use to intelligently evaluate the psychologist's findings. Discussion with the psychologist is often necessary, as numerical and descriptive reports may require clarification.

The Working Hypothesis

When the diagnostic study is completed, the clinician has the task of equating and correlating the findings to plan a treatment program. A logical hypothesis of the dynamics of the problem requires a formulation. At this juncture the physician may ask himself, "Is this behavior problem a result of failure on the part of patients, teachers, etc. to recognize and accept a defect in the child's cerebral function?" If it seems so, the solution to the problem is to help the parents develop insight into and understanding of the child's deficiency. If, on the other hand, the neurologically handicapped child is reacting adversely to the tensions in his family, the possibility of psychiatric help must be considered.

The Therapeutic Test

If the diagnosis formulation is correct and the adults in the child's environment are adequate to develop an understanding and acceptance of the handicapped child, the problems in behavior are dramatically resolved — often permanently. In the severely handicapped child, situational problems at school will recur whenever school facilities are inadequate. These are most often understood and readily improved through the efforts of the school administrators without the physician being involved.

Continued

It is my observation that almost any kind of therapy directed at childhood behavior problems (regardless of their cause) may result in temporary improvement of behavior; however, nonspecific therapy does not result in the permanent solution of the problem. Arbitrarily, therefore, I have stipulated a three-year period of freedom from behavior problems when due primarily to an unrecognized cerebral dysfunction. Most children with a behavior problem related to more deeply rooted problems, often in the family, can be expected to have recurrent symptoms before three years have elapsed.

Prevention

Early diagnosis and interpretation of the child's handicap to the parents and teachers can be a real assistance in preventing those frustrating and embarrassing situations for the child which frequently develop into behavior problems. The child whose teacher is aware of his inability to skip and cut and draw can satisfactorily be spared the experience of repeated failures in this area. Many handicaps heretofore unrecognized, until a serious school behavior problem develops, can now be diagnosed in the preschool years and therapeutic measures instituted.

Treatment

The combination of understanding and acceptance by the adults dealing with the child is still the keynote of therapy. Interpretation is offered the parents according to their ability to grasp it. Fortunately, problems in the areas of neuromuscular activity, the sensorium, sensory perception, and cerebral perception are understood without difficulty. Problems related to impulse control are more difficult to deal with. Here the judicious use of the book, *The Other Child,*[1] may be helpful. The parents need to understand that the child requires firm, patient disciplinary support from them. They may get it from careful reading of this book and help from an understanding physician.

The beneficial results of environmental manipulation such as special schools transferring to smaller classrooms, avoiding such stimulating, unsupervised groups as are found on the school bus, the playground or in the lunchroom supplement parents' efforts in an effective way.

The conference between the physician and teacher has been an effective diagnostic tool as well as therapeutic device. The physician's objectivity is often helpful to the teacher, since he can often interpret the child to the teacher, thus increasing her understanding and acceptance of him and his limitations. It is unnecessary to ask special favors for the child. Such a conference, when it occurs in a stable school situation, invariably enhances increased cooperation between the school administrators and the parents. People in school administration are becoming increasingly aware of the needs of this group, and as a result, school resources are developing programs for their educational needs. Strauss and Lehtinen[2] deal thoroughly with the educational aspects of this problem.

A healthy on-going child-family-physician relationship is encouraged during and following the period of treatment. Parents of children with neurologic handicaps need a physcian with whom they can periodically consider their child's problems as new and different stressful situations develop.

Drug therapy can be judiciously used, always on an individual basis. In my own therapeutic program it plays a very minor role. Currently only four patients are on drugs: two on amphetamine sulfate, one on prochlorperazine, and one on reserpine. In my own experience, prolonged use of drugs is unnecessary. They may be useful on occasion for easing a patient and his family over a stressful situation, but the development of understanding and acceptance by parents is actually the only treatment that promises resolution of the problem.

One last word. In this, as in so many other areas of clinical medicine, the physician's attitude is a limiting and crucial factor in the area of diagnosis and treatment. Only if he is patient, sensitive, enthusiastic and hopeful about the possibility of improving the child's adjustment can he successfully influence other factors important in the child's every day life.

The Blue-Glass Cure

Strikingly and pathetically naive among the many cures enjoying popular favor and testimonial endorsement in the last century was the blue-glass cure.

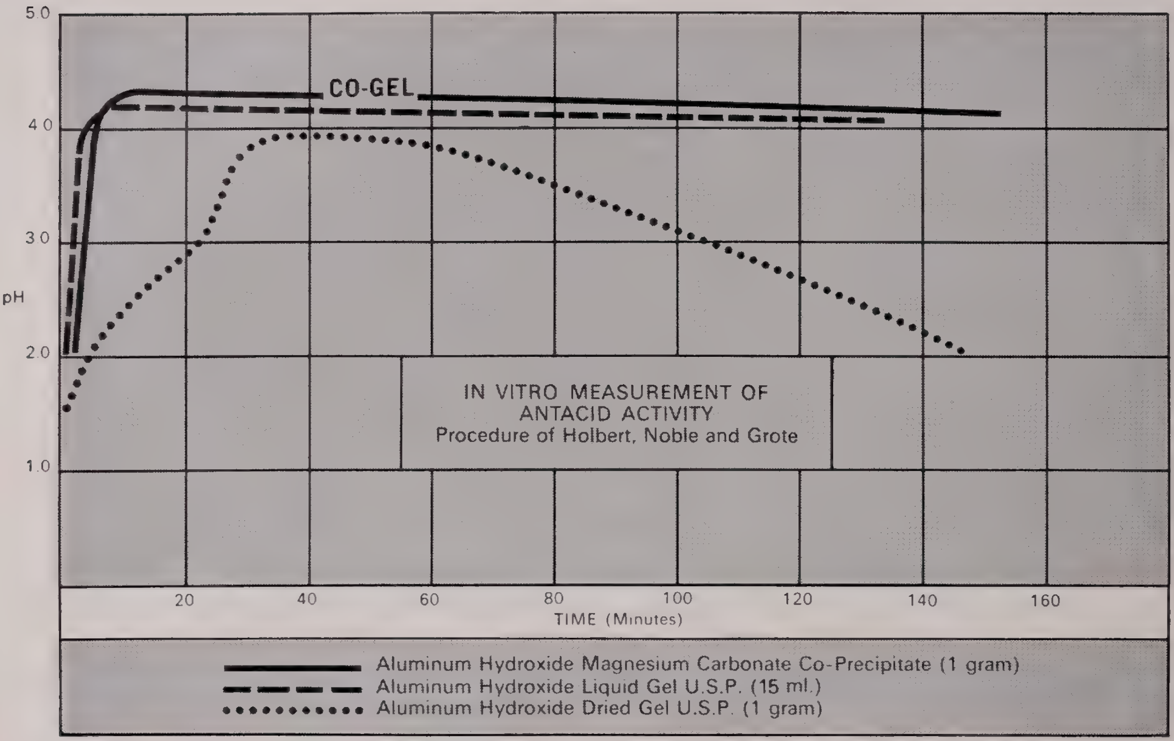
Because of a clerk's inadvertent blunder a glass-making firm was disconcerted one day to find itself with a large supply of unmarketable blue glass on hand. Anxious to dispose of this surplus without loss the firm offered a salesman a handsome bonus if he could contrive to sell the glass. Thus financially motivated, the salesman asked a scientific friend whether he could suggest any new uses for blue glass other than the conventional ones; to which his friend jokingly replied that since the blue end of the spectrum furnished actinic rays with photochemical properties, perhaps light rays through blue glass might possess some therapeutic value.

That was all the enterprising salesman needed! He proceeded to advertise the curatively-endowed blue glass so successfully that the supply promptly disappeared and the firm had to manufacture more blue glass to satisfy the local demand, which soon expanded into a national one, inducing other glass foundries also to engage in the lucrative manufacture of blue glass for multitudes of eager customers. Particularly gullible were Civil War veterans, both north and south, who alleged with conviction that naked exposure of their old wounds to the rays of light through the blue glass made the chronically bothersome aches and pains vanish.

In time, however, as the glass appeared to lose its potency, the craze waned. Disillusionment set in and the fickle public relegated its blue glass to the attic, from which, who knows, it may some day be resurrected, should some later generation decide to revive an earlier allegiance. Such revivals have been known to occur! Ironically, when the blue-glass craze was over, surplus blue glass again became "a drug on the market."

CO-GEL

THE NEW ANTACID



Holbert, J. M., Noble, N., and Grote, I. W.—Jnl. Amer. Pharm. Assoc. (Sci. Ed.) 37,292 (1948).

Now, an antacid tablet with the effectiveness of a liquid!

CO-GEL is not just another antacid, but rather it's an entirely *new antacid compound* for gastritis, hyperacidity and peptic ulcers. It is an Aluminum Hydroxide formulation with Magnesium Carbonate Co-Precipitate. The Co-Precipitate, a new chemical, gives CO-GEL Tablets the speed of action and the duration of a liquid antacid.

The above chart compares the antacid action of the COGEL Tablet formula with both liquid and dry $Al(OH)_3$. Notice that CO-GEL neutralizes acid faster than $Al(OH)_3$ dried gel tablets and has a prolonged buffering action. The CO-GEL curve parallels that of liquid $Al(OH)_3$.

Liquid CO-GEL, containing the Co-Precipitate, is also available. CO-GEL is reasonably priced to the patient. Availability: CO-GEL Tablets (bottles of 100 and 1,000) CO-GEL Liquid (pints and gallons).

For complete information and samples, write to Dept. MM-103.

FORMULA

Each CO-GEL Tablet, and teaspoonful of CO-GEL Liquid, contains 330 mg. of Aluminum Hydroxide Magnesium Carbonate Co-Precipitate. Tablets have a chewable base. Both forms are mint flavored.

CONTRAINDICATIONS

None.

DOSAGE

For relief of hyperacidity, peptic ulcers or gastritis, chew one tablet (or take one teaspoonful). Repeat in 1 hr. if necessary.

Medical Seminar

The Penicillins

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

PENICILLIN IS A generic term applied to an entire group of natural and semisynthetic antibiotics having a common nucleus, six aminopenicillanic acid (6-APA). These antibiotics have bactericidal action against many gram-positive and some gram-negative organisms. This group of drugs (1) has the same nucleus, (2) in general, shares cross antigenicity,* and (3) exerts its bactericidal effect in the same manner.

History of Penicillins

In 1929 Fleming, while at St. Marys Hospital, London, working on staphylococcal variants, noted that certain contaminating molds produced lysis of the staphylococci growing in cultures. He isolated the substance and named it penicillin after the mold producing it *(Penicillium notatum)*. With this substance, he conducted small-scale experiments in wound infections, but because of the small amount and crudeness of the product his work attracted little attention.

Penicillin remained of only academic interest until 1939 when Florey at Oxford launched the work that resulted in penicillin's application to clinical medicine. In 1940 Chain purified benzyl penicillin (penicillin G) from a substance produced by the mold, *P. notatum*.

An intensive developmental program was launched in Great Britain and the United States to develop the drug for use in World War II. Clinical trials were carried out at Yale and the Mayo Clinic in 1942 with encouraging results.[1,2] Further trials were conducted in the North African Theater of Operations in 1943, with success in the prophylaxis and treatment of wounds and in certain medical illnesses. Penicillin was rapidly accepted into the armamentarium of the armed services and was released for general clinical use shortly after World War II.

In 1945 Fleming, Florey, and Chain were awarded the Nobel Prize in Medicine for the development of penicillin.

In 1958 Sheehan isolated and produced the nucleus of the penicillin molecule, 6-APA. This opened the door for the chemical attachment of differing side chains and eventually resulted in the production of the new semisynthetic penicillins. In 1960 Doyle produced methicillin, the first semisynthetic penicillin active against penicillin-G resistant staphylococci.[2-4]

Classification of Penicillins

The penicillins may be divided into two groups: natural and semisynthetic. The natural penicillins are produced by the fermentation of the mold *Penicillium*, particularly *P. notatum* and *P. chrysogenum*. The semisynthetic penicillins are the result of chemically adding a different side chain to the 6-APA nucleus — the 6-APA nucleus being produced by the natural fermentation process; hence the term semisynthetic.

Natural Penicillins

The natural penicillins include: penicillins G, V, O, and N.

Continued

---

*See Test Your Word Score Page 447.

Penicillin O is of interest because, originally, it was believed to have no cross-antigenicity with penicillin G and, therefore, would be of use in treating patients who were allergic to penicillin G. However, this has not proved to be the case, and penicillin O currently is of little clinical importance.

Penicillin N is a penicillin with a straight side chain rather than a benzyl side chain and is produced by the *Cephalosporium* organisms. Formerly known as cephalosporin N, it was renamed because it contained the 6-APA nucleus. The *Cephalosporium* organisms also produce substances with a slightly different nucleus from which the drug cephalothin (Keflin) has been derived.[3,5] There are other natural penicillins such as F, K, and X, currently of little clinical interest.

Semisynthetic Penicillins

These include (1) phenethicillin, (2) methicillin, (3) nafcillin, (4) oxacillin, (5) cloxacillin, and (6) ampicillin. To date more than 500 semisynthetic penicillins have been produced, a number of which are currently being evaluated clinically.

The Chemistry of Penicillins

The chemistry of the penicillins involves the nucleus 6 aminopenicillanic acid and a distinct side chain for each penicillin. The nucleus 6-APA is made up of a thiazolidine ring and a beta-lactam ring. The differing side chains seem to be responsible for the differing properties of the semisynthetic penicillins, including one or a combination of the three following characteristics: (1) acid resistance, resulting in absorption from the gastrointestinal tract, (2) penicillinase resistance, resulting in activity against penicillin-G resistant staphylococci, and (3) a broader spectrum of activity, with effectiveness against more gram-negative organisms.

Penicillinase is an enzyme produced by certain strains of *Staphylococcus* and *Bacillus cereus*, as well as other organisms, which acts to catalyze the enzymatic hydrolysis of penicillin G in opening the beta-lactam ring, producing penicilloic acid which has no antibacterial activity and which is relatively nonallergenic.[3]

Mode of Action of the Penicillins

The mode of action of all the penicillins in accomplishing their bactericidal effect is the destruction of the bacterial cell wall. The exact mechanism remains unknown but it seems to inhibit one or more enzymes, lead-

TABLE I
Natural and Semisynthetic Penicillins

Drug	Route of Administration	Indication
	Natural	
Penicillin G	Parenteral	Susceptible organisms*
Penicillin V (Compocillin-VK, V-Cillin, Pen Vee)	Oral	Susceptible organisms
	Semisynthetic	
Phenethicillin (Maxipen, Syncillin, Darcil, Ro-Cillin)	Oral	Susceptible organisms
Methicillin (Staphcillin, Dimocillin-RT)	Parenteral	Penicillin G-resistant staphylococci
Nafcillin (Unipen)	Oral, parenteral	Penicillin G-resistant staphylococci
Oxacillin (Resistopen, Prostaphlin)	Oral, parenteral	Penicillin G-resistant staphylococci
Cloxacillin (Tegopen)	Oral (parenteral not yet commercially available)	Penicillin G-resistant staphylococci
Ampicillin (Polycillin, Penbritin)	Oral, parenteral	Susceptible organisms, a broader spectrum of activity

*Susceptible organisms are gram-positive organisms excluding resistant staphylococci and including the gram-negative Neisseria.

ing to the accumulation of cell-wall precursors in affected bacteria. The penicillins thus inhibit the synthesis of essential cell-wall components or their assembly.

This is a fortunate fact of comparative histology; the substances making up the bacterial cell wall are highly vulnerable to penicillin, but the mammalian host cells are largely unaffected.[6]

Clinical Grouping

A clinical grouping of the penicillins of current importance is shown in Table 1.

Natural Penicillins

Penicillin G is still the most effective penicillin against *susceptible* organisms. Organisms against which penicillin G is the drug of choice are shown in Table 2.

Penicillin G or V, depending on the route of administration selected, is the drug of choice in the prophylaxis against rheumatic fever, endocarditis in valvular heart disease, lymphangitis, glomerulonephritis, and venereal disease.

Penicillin G is available in several forms: (1) aqueous crystalline for intravenous or intramuscular injection, giving rapid absorption and then excretion in three to six hours; (2) aqueous procaine, a repository form giving blood levels that persist from 12 to 24 hours; (3) benzanthine penicillin (Bicillin) for obtaining blood levels that persist from two to four weeks, and (4) PAM, procaine penicillin G in oil containing 2% aluminum monostearate, giving blood levels that last four days, used extensively by public health authorities in the treatment of gonorrhea and syphilis.

Penicillin G is also available in oral form, but its absorption is not as complete as that of penicillin V. Doses of penicillin G are varied with the organism and clinical situation and are, in general, well known. Currently, penicillin G is available primarily as the potassium salt with 1.5 mEq. of potassium present in each 1,000,000 units. As the sodium salt, penicillin G contains 0.1 gm. of sodium for each 1,000,000 units. These values must be considered in those patients with renal or cardiac disease or those receiving high doses intravenously.[7-9] Less well known is the effectiveness of penicillin G against some gram-negative bacilli, chiefly *Escherichia coli* and some strains of *Proteus mirabilis.*

The second natural penicillin of clinical importance is penicillin V. This drug is more effectively absorbed from the gastrointestinal tract than is penicillin G and gives higher blood levels which persist longer on oral administration than does penicillin G.[10] The absorption of penicillin V is not affected by the presence of food, as contrasted with phenethicillin. The acid-resistant quality of penicillin V gives it the advantage of being absorbed from the gastrointestinal tract. Therefore, penicillin V is used in mild infections in which the oral route is indicated. Studies[11] have indicated that it is effective in preventing endocarditis in valvular heart disease in patients undergoing oral surgery, when given in a dose of 500 mg. every six hours 24 hours prior to and continued for the 48 hours after surgery. Penicillin V in amounts of 125 mg. (200,000 units) or 250 mg. (400,000 units) given two to four times daily the first week of each month may prevent recurrent lymphangitis and consequent lymphedema. Usual doses are 125 mg. (200,000 units) every six hours for minor infections, and as much as 500 mg. (800,000 units) every four to six hours in more severe infections. Side effects include mild gastrointestinal irritation manifested by abdominal cramping and an increased number of stools that tend to be liquid.

TABLE 2
Organisms Against Which Penicillin G is the Drug of Choice

1. Diplococcus pneumoniae
2. Streptococcus pyogenes (beta-hemolytic streptococci)
3. Streptococcus viridans (Streptococcus mitis)
4. Enterococcus (Streptococcus faecalis) (when penicillin G is combined with streptomycin)
5. Staphylococcus aureus (nonpenicillinase producing)
6. Neisseria gonorrhoeae
7. Treponema pallidum
8. Neisseria meningitidis (intracellularis)
9. Fusospirochetes (Vincents')
10. Borrelia (relapsing fever)
11. Spirillum minus (rat-bite fever)
12. Streptobacillus moniliformis (rat-bite fever)
13. Clostridium
14. Actinomyces bovis
15. Bacillus anthracis
16. Listeria monocytogenes
17. Erysipelothrix insidiosa (erysipeloid)
18. Pasteurella multocida

Continued

In summary, the natural penicillins G and V are unsurpassed in the treatment of susceptible organisms and remain the drugs of choice in infections due to susceptible organisms: penicillin G parenterally and penicillin V orally.

Semisynthetic Penicillins

Phenethicillin was the first of the semisynthetic penicillins. It has the property of being acid-stable and, therefore, may be taken orally. However, food interferes with its absorption, as contrasted with penicillin V. Phenethicillin gives a higher blood concentration than does penicillin V but has no greater bactericidal effect, as determined by serum bactericidal tests. At the present time, phenethicillin acts essentially the same as penicillin V and thus may be used interchangeably, if the drug is given to a patient in the fasting state. The drug is appropriate for mild-to-moderate infections due to susceptible organisms, but it has no appreciable clinical effect on penicillinase-producing staphylococci. Phenethicillin is administered orally in a dose similar to that of penicillin V: 125 mg. (200,000 units), 250 mg. (400,000 units), or 500 mg. (800,000 units) by mouth every four to eight hours.

The first of four penicillinase-resistant semisynthetic penicillins (PRSP) to be discussed is methicillin. This drug was the first of the group of PRSP penicillins. Not being acid-stable, methicillin has two clinical properties. (1) It is not absorbed from the gastrointestinal tract and must be given parenterally; and (2) it should not be given in large volumes of intravenous solutions administered over several hours. The solutions may be relatively acid and the drug may be inactivated; therefore, if given in intravenous solution, it should be in 100- to 250-ml. solutions administered over one to two hours. Methicillin's main clinical use is against penicillin-G resistant staphylococci, which are defined as those requiring more than 1.0 μg per milliliter of penicillin G for inhibition. Methicillin is not inactivated by staphylococcal penicillinase, regardless of inoculum size. Against susceptible staphylococci, streptococci, and pneumonococci, methicillin has only about ⅓ the activity on a weight basis as has penicillin G. Methicillin has little effect against enterococci and no synergistic effect against enterococci when administered with streptomycin. The drug is less bound to plasma protein than are the other PRSP; but the significance of this is unknown. Some laboratory and clinical strains of staphylococci are resistant to methicillin; this has been noted in Great Britain particularly and on the European continent. As yet, clinical resistance has not become a serious problem in the United States.

The mechanism of steric hindrance has been proposed as the explanation of methicillin's resistance to penicillinase. This theory postulates that the inability of penicillinase to hydrolize methicillin and other PRSP is due to inability of the active sites of the enzyme to achieve sufficient contact with the specific groups of the penicillin. The methoxy groups attached to the benzene ring in the side chain of methicillin may be responsible for its steric hindrance.

Rare side effects of methicillin therapy include eosinophilia, neutropenia, and nephrotoxicity as manifested by proteinuria and hematuria. Overgrowth with gram-negative organisms has been a problem in some patients treated with methicillin.

The dose of methicillin is 1 to 2 gm. given intravenously or intramuscularly every two to six hours, with a maximal effective daily dose of 12 to 24 gm.

Nafcillin, oxacillin, and cloxacillin are similar in their clinical characteristics and effectiveness. These three semisynthetic penicillins have the same two qualities: acid resistance and penicillinase resistance. Therefore, they can be orally absorbed and are effective against resistant staphylococci. These drugs have biliary excretion and enterohepatic recirculation. Each has a higher serum protein binding than does methicillin, but the significance of this is unknown. The oral forms of these drugs give minor gastrointestinal side effects. When given orally, these drugs are absorbed best when the patient is fasting. Even in the fasting state, oral absorption is variable from individual to individual and is very poor in some patients.

Therefore, in serious infections the parenteral preparations of these drugs are preferred.

Nafcillin is more active against gram-positive susceptible organisms than is methicillin but, like oxacillin and cloxacillin, is still less effective than is penicillin G against susceptible organisms.

The same strains of staphylococci that are resistant to methicillin show increased resistance to these three drugs. (Thus far, this is not a clinical problem in the United States.)

Oxacillin is not excreted in sweat. Staphylococci may be cultured from pyoderma during treatment. Oxacillin's diffusion into serous cavities is poor.

Serum levels with cloxacillin are higher than those with oxacillin, but cloxacillin is eliminated more rapidly. Cloxacillin is only ¼ as active against pneumococci as is oxacillin.

The dosages for these three semisynthetic drugs are as follows: nafcillin, oral 250 mg. to 1 gm. every four to six hours, intramuscular 500 mg. every four to six hours, and intravenous 3 to 6 gm. per day; oxacillin, oral 500 mg. to 1 gm. every four to six hours, and intramuscular 500 mg. every four to six hours; cloxacillin, oral 500 mg. every four to six hours, and intramuscular 500 mg. every four to six hours. (Parenteral form is investigational at this time.) Oral forms should be given in the fasting state. In rare instances, oxacillin and cloxacillin may produce asymptomatic rises in serum glutamic oxaloacetic transaminase.

In summary, oxacillin, cloxacillin, and nafcillin given by the oral route appear to be equally effective clinically. Because these drugs are acid-resistant, they can be taken orally. They have biliary excretion and enterohepatic recirculation and have higher serum protein binding than does methicillin, but the significance of this is unknown. The oral products give mild gastrointestinal side effects.

Methicillin is not acid-resistant and must be given parenterally. Parenteral forms of oxacillin, cloxacillin, and nafcillin are approximately equal in clinical results to methicillin in the treatment of resistant staphylococcal infections.[12] These drugs are indicated in penicillinase-producing staphylococcal infections. None of these drugs (oxacillin, cloxacillin, nafcillin, methicillin) is as effective as penicillin G in the treatment of susceptible organisms.

Ampicillin differs from those previously discussed because (1) it is acid-resistant and, therefore, is absorbed orally, (2) it has a "broader" spectrum of activity, and (3) it has no effect against penicillin-G resistant staphylococci. It is only ¼ to ½ as effective against susceptible organisms as is penicillin G. Ampicillin is effective against some strains of *E. coli*, *P. mirabilis*, *Salmonella*, *Shigella*, *Haemophilus influenzae*, para-influenzal organisms, *Brucella*, and *Bacteroides*. The drug is not effective against the *Klebsiella-Aerobacter* group, *Pseudomonas* organisms, or some strains of *Proteus* (those that are indole producing). It has greater invitro activity against enterococci than do the other semisynthetic penicillins. Serum levels are not lessened when ampicillin is taken with food. The drug is not markedly bound to serum protein. Its concentration in bile is 300 times that in plasma. Ampicillin has a high biliary excretion and enterohepatic recirculation. Like penicillin G, ampicillin is inactivated by penicillinase and, therefore, has no place in the management of resistant staphylococcal infections. Chief interest in the drug has been in the management of (1) urinary tract infections, (2) enteric infections, including *Salmonella* carriers, and (3) chronic bronchopulmonary disease.[4] The dose is 500 mg. every four to six hours by mouth. The intramuscular dose recently made available is the same. Side effects include an asymptomatic rise in serum glutamic oxaloacetic transaminase in children.

The blood levels of all penicillins may be increased by the administration of probenecid (Benemid). This drug blocks the tubular excretion of penicillin by competitive inhibition: an important pharmacologic effect, since 80% of penicillin G is excreted by the renal tubule and only 20% by glomerular filtration. However, probenecid itself may cause hypersensitivity reactions.

Continued

Anaphylactoid reactions, fever, chills, rash, or anemia may be produced. The drug may also give a positive result to the Benedict test for reducing substance in the urine. Some patients are unable to tolerate the drug because of gastrointestinal irritation. Therefore, some physicians do not administer probenecid because it may confuse the clinical picture of the disease process itself or of the penicillin therapy. The usual dose is 0.5 gram by mouth every six hours.

Untoward Reactions

Allergy

This constitutes the most serious problem in penicillin therapy. Since all penicillins contain the 6-APA nucleus, if a patient is allergic to one penicillin, he may well be allergic to the others. It is estimated that allergic reactions occur in as many as 10% of patients receiving penicillin. The reactions include (1) skin reactions, (2) drug fever, (3) anaphylactoid reactions, (4) serum sickness, (5) toxic psychoses, and (6) hematemesis from urticaria of the gastrointestinal tract.

A recent study[4] found that the incidence of cutaneous reactions varied from 2.9 to 4.8%. In 793 cases of anaphylactoid shock, 72 deaths occurred, a 9% mortality rate.[4] Most likely to have a reaction are those who have received repeated doses, those who are in the 20 to 50-year age group, and those who have a history of atopy (hay fever, asthma, urticaria). The least likely mode of administration to cause a reaction is the oral; in one series, 0.5% reactions occurred. Intramuscular procaine penicillin was next with 1.4%, and intramuscular benzanthine penicillin was third with 3.8%. Topical penicillin is believed to produce the highest incidence of allergy.

When a patient is given his first injection of penicillin, he should be observed for 30 minutes after the injection; for symptoms of an anaphylactoid reaction usually occur within 10 minutes. Methods including skin testing, conjunctival testing, hemagglutination tests, passive transfer tests, and skin testing with penicilloyl-polylysine have all failed to detect those who later had serious reactions to injected penicillin. Also, even minute quantities of penicillin used in the testing solution have resulted in serious allergic reactions.

The treatment of an allergic reaction involves (1) adrenalin, (2) diphenhydramine hydrochloride (Benadryl), (3) penicillinase (may give an allergic reaction itself), (4) steroids (may be hazardous in a serious infection), and (5) maintenance of an adequate airway.

Penicillinase (Neutrapen) is produced from *B. cereus*. The dose is 800,000 units intramuscularly or intravenously, depending on the seriousness of the reaction, and may be repeated after three days. No more than three such doses should be administered during any one illness.

Toxicity

Direct toxicity to the mammalian host cells by the penicillins is rare and is manifested chiefly in the form of convulsions when very high doses are used (60 to 100,000,000 units per day). However, most normal patients can tolerate these doses.

Toxicity due to the salts contained in the penicillins is a hazard in patients with cardiac disease or renal disease or in those receiving high doses intravenously, as has been mentioned previously.

Indirect toxicity is present in two forms: (1) overgrowth with gram-negative organisms due to suppression of competitive flora, and (2) Herxheimer reactions that occur chiefly in the therapy of syphilis, resulting in chills, rise in temperature, malaise, muscle aching, and, at times, focal neurologic signs.

Clinical Path Conference

Hemoptysis and Uremia

Case Report

A 61-year-old married white male was admitted to the Swedish Hospital on December 16, 1964, because of hemoptysis. One month previously he had experienced pain in multiple joints and was seen by his physician who made a diagnosis of acute arthritis. The joint pain was restricted to the hips and knees and was diagnosed as osteoarthritis. He was treated with sodium salicylate. Although his joint pain improved, he continued to have malaise and developed anorexia with a weight loss of 20 pounds. In retrospect, he stated that he had not felt well since a hemorrhoidectomy the previous July. His long-term complaints were fatigue, weakness, and malaise, and a slow decline in body weight. There was no story of previous hemoptysis, night sweats or fever.

Physical Examination

On physical examination he was pale with labored respirations. The blood pressure was 160/118, the pulse was 75 and regular, and the temperature was 98.5°. The patient's body showed the effects of weight loss. His heart sounds were normal without murmurs. Diffuse rales were heard in the chest, and the breath sounds were distant. No abdominal masses were felt. The abdomen was soft without tenderness. Peripheral and periorbital edema was absent. The joints were not tender, swollen, or deformed. There was no skin rash.

Laboratory

The laboratory studies included a hemoglobin of 7.4 gm%, a hematocrit of 23.5%, and a white blood cell count of 12,200 with 89 polymorphonuclear leucocytes. The peripheral smear was hypochromic and microscopic with moderate anisocytosis. Urinalysis showed a specific gravity of 1.010, 2+ albumin, 3-6 wbc/hpf, numerous rbc/hpf, and 14-18 granular casts/hpf. The stools were negative for occult blood. The blood urea nitrogen was 111 mg./100 ml. The sputum culture showed a moderate growth of *A. aerogenes.*

X-ray studies of the chest, gastrointestinal tract, and urinary tract were performed.

Course

The patient remained weak and anorectic and on December 18 had three episodes of coughing up small amounts of blood. On December 19 he became quite dyspneic, perspired and had a pulse of 112. His blood pressure fluctuated from 170/100 to 200/140. Because of continued dyspnea he was placed in oxygen. He continued to cough up blood-stained mucous and frothy fluid. He was given three units of packed cells for his anemia, but there was no change in his condition. He continued to perspire profusely and lapsed into coma. He died on December 21 — five days after admission.

Dr. Charles Kolars:*

Before I discuss the differential diagnosis, I would like Dr. Mork to give us his interpretation of the x-ray studies.

---

*Attending internist, St. Barnabas Hospital.

Continued

Discussion of X-Rays

Dr. Frank Mork, Jr.:*

A film of the chest taken December 16 shows a diffuse mottled opacification of the left lung and a patchy area of infiltration in the right lower lobe (Figure 1). The costophrenic angles appear clear. I do not see any pleural fluid. The heart demonstrates left ventricular hypertrophy with a cardiothoracic index of 54%. The aorta is slightly ectatic. I see no masses in the chest and no hilar or mediastinal adenopathy. A repeat chest x-ray on December 19 shows no change in the left lung, but there is a progression in the right lung with mottled increased density occupying the right upper lobe (Figure 2). The costophrenic angles are still clear. There is no change in the heart size. A stomach examination was performed and was negative. An intravenous pyelogram was obtained December 19. The preliminary scout film shows the kidneys to be normal in size, shape and position. There is no calcification in the parenchyma. The intravenous pyelogram fails to visualize in three hours, indicating decreased renal function. The lung picture suggests several possibilities. One is a diffuse pneumonic process such as a fulminating gram-negative pneumonia. A further possibility is atypical pulmonary edema. This would fit nicely with the cardiac enlargement, but the lack of pleural fluid is against it. A third possibility from roentgen standpoint would be pulmonary hemorrhage associated with renal disease.

Differential Diagnosis

Dr. Kolars:

This is the case of a 61-year-old man who was admitted with evidence of renal disease and a rapidly explosive pulmonary picture with death five

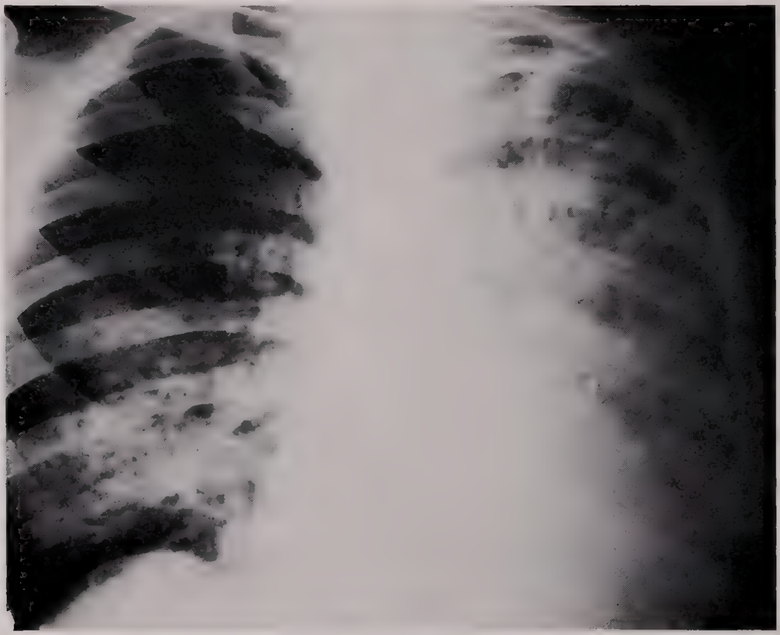

Fig. 1 — Initial film of chest taken on December 16th, showing patchy infiltration, most extensive in left lung. The heart appears slightly enlarged.

---

*Radiologist, St. Barnabas Hospital.

days after admission. We have a hint that he had been in ill health for approximately six months. The exact characteristics of that ill health were not defined until about a month before his admission, when he had an isolated episode of arthritis. I assume the arthritis was not a recurring problem. The laboratory findings on admission indicate renal disease, and I would like to spend some time on this aspect.

Renal Disease

He had an elevated BUN and evidence of glomerulitis on urinalysis. The specific gravity is 1.010. This is probably a fixed specific gravity and indicates a severe degree of renal impairment. With the hemoglobin of 7.4 grams in the absence of any other blood loss one would tend to relate the anemia to chronic renal insufficiency.

I assume that the renal problem had been present for some time, but the normal-sized kidneys suggest that this has not been long-standing renal disease. It may be of several months' duration. Superimposed on the kidney disease is an acute pulmonary problem which spreads rapidly and leads to his death within five days.

Either this patient has a renal disease and a process in his lung which leads to his death or he has a systemic disease which is expressing itself in the lungs and the kidneys. I will leave the renal problem temporarily and concentrate on the pulmonary problem.

Infection

Infection is a consideration. The sputum was frothy and blood-tinged, and one culture showed a moderate growth of *Aerobacter aerogenes. Aerobacter aerogenes* is serologically indistinguishable from a *Klebsiella* or a Friedlander's type of bacillus. The genus of *Klebsiella* is felt now to include *Aerobacter.* Are we dealing with a severe Friedlander's pneumonia

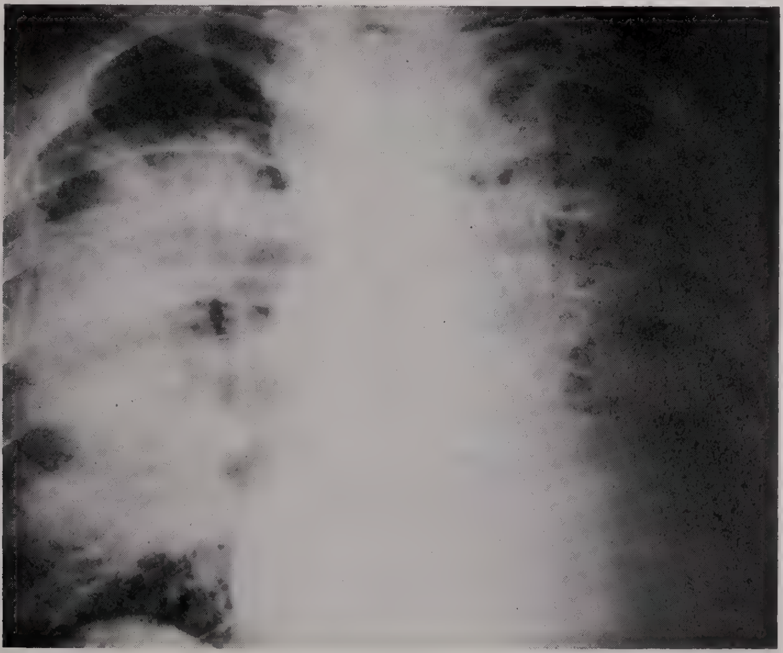

Fig. 2 — Film of chest three days after admission, demonstrating rapid progression of infiltration process into right lung and diffuse mottling of both lung fields.

Continued

which was rapidly progressive and superimposed on a pre-existing renal lesion? The film is against this. On the first film there is infiltration in the left lung with the beginning infiltration in the right (Figure 1). But three days later the left lung infiltration has not changed much. It remains the same, but there is an increase on the right side (Figure 2). If this were a Friedlander's pneumonia in its toxic progressive form, I would have expected further change in the left lung. Because the left lung remains relatively stable, because he is not febrile, and because he has a relatively low white count, I have to rule out infection.

Uremic Pneumonitis

Is uremic pneumonitis a logical diagnosis? Usually with the pneumonia of uremia, the BUN progressively rises and, in my experience, has been much higher than 111 mg./100 ml. and rising rapidly. Also, it is usually a diffuse process, and the left lung would not remain stable while changes in the right lung advanced. Is it pulmonary edema? If it were pulmonary edema I would have expected diffuse changes in both lungs.

Hemorrhagic Lungs and Vasculitis

Let's return to Dr. Mork's original suggestion of hemorrhage. This could account for the non-parallel changes in the two lungs. What could give the patient such a hemorrhage? A systemic process might involve both the lung and the kidney. Both a systemic vasculitis with involvement of medium and small blood vessels and an allergic or idiopathic vasculitis are possibilities. These may be expressed as specific disease entities such as periarteritis nodosa, Wegener's granulomatosis, or collagen disease such as lupus. Wegener's granulomatosis is unlikely because of the absence of a history of upper respiratory disease and purulent sinusitis. This disease is characterized by a generalized granulomatous vasculitis. It is usually initiated by a sinus problem and results in lung involvement and finally in renal failure. Periarteritis nodosa involving the lungs is almost invariably associated with an eosinophilia in the peripheral count, particularly if it involves the lungs to this extent. If it were a periarteritis nodosa, I don't think we could explain the rapid progression in this lung picture entirely on the basis of the nodular or vascular lesions.

Goodpasture's Syndrome

Another grouping vasculitis syndrome of more interest in recent years is Goodpasture's syndrome.[1] He had had a patient with pulmonary hemorrhage and renal glomerulitis who he felt had influenza during the pandemic of 1918-1919. This patient had an arteritis of the splenic vessels. The disease was resurrected in about 1958, and many cases have been described since. It is a disease which usually affects young males, but cases have been reported up to the age of 71 and down to the age of 13. It is a brief and fatal illness lasting anywhere from two weeks to three years, with the average being about six months.

It is almost always characterized by repeated pulmonary hemorrhages with hemoptysis. This is usually enough to produce an iron deficiency anemia. The anemia is attributed to a loss of iron into the alveoli, and pulmonary hemosiderosis is a common complication. This iron becomes sequestered and is not available for recirculation.

Renal disease almost invariably follows the pulmonary disease. There are cases on record in which the renal disease develops extremely rapidly. In one case the person went from a normal urine to a biopsy-documented glomerulonephritis within three months. Some patients are admitted with pulmonary infiltrates with the anemia down as low as 3 to 4 grams but with relatively normal renal function. They then lapse into terminal renal failure.

Does this patient have Goodpasture's syndrome? The fact that the renal disease precedes the explosive terminal lung changes is atypical. In most cases of Goodpasture's the hemoptysis is a forerunner of uremia. There is controversy as to whether this is a distinct entity or just another unusual expression of a systemic vasculitis. Formerly, periarteritis was thought to be a diffuse disease involving primarily the medium-sized vessels, leading invariably to death. We know now that some cases of "periarteritis" are really a hypersensitivity angitis and are reversible. Their expression may be limited to the lung and the kidney. Of the approximately 53 cases of Goodpasture's that have been reported, six cases had evidence of arteritis in other organs. There are other authors who contend vigorously that Goodpasture's is not a vasculitis because they rarely find evidence of arteritis in the hemorrhagic lungs. Whether Goodpasture's is an arteritis or a distinct entity involving only lung and kidney is controversial. In any case, the pulmonary hemorrhage usually occurs before the glomerulonephritis.

Summary

We have a 61-year-old man who has been ill for six months and who dies with lung and kidney disease. I think he had a nonspecific vasculitis. I will not label it periarteritis specifically. I think periarteritis nodosa is unlikely because of the absence of eosinophilia. Goodpasture's syndrome seems as good a classification as any, whether or not arteritis was present. Secondly, he could have had a simple subacute glomerulonephritis with a superimposed infection, but I consider this less likely. Other possibilities are lupus erythematosus or a malignant type of rheumatoid arthritis. In the latter, extensive lung changes may be present but there is usually more evidence of arthritis. This man really didn't have a characteristic type of rheumatoid arthritis. I think we are dealing with a pulmonary-renal syndrome with the basic pathological events being manifestations of a vasculitis with probable hemorrhage into the lung.

Dr. Kolar's Diagnosis: Goodpasture's Syndrome.
Dr. Philip Olson:*

There is one other situation where you get diffuse pulmonary changes — alveolar cell carcinoma. Although patients with alveolar carcinoma seldom develop sudden changes in the lungs, they do have sudden pulmonary hemorrhages. The statement about frothy, copious secretions suggests alveolar cell carcinoma. In this carcinoma, copious amounts of sputum are the rule. Pulmonary hemorrhages and pulmonary infarct also occur.

Dr. Lyle Hay:**

Did he have any vomiting in these last few days?

---

*Radiologist, St. Barnabas Hospital.

**Director of Medical Education, St. Barnabas Hospital.

Continued

Dr. Richard Reece:*

No, there was some confusion originally as to whether he had hematemesis or hemoptysis. With the negative Guaiac, gastrointestinal bleeding was dropped from consideration.

Pathology Discussion

Dr. Reece:

I will start with the autopsy observations: This heart weighed 520 grams and showed left ventricular hypertrophy. It displayed mild arteriosclerosis but no occlusions. The lungs were very heavy. The right weighed 1000 grams and the left 900 grams. Both exhibited purplish discoloration on the pleural surfaces. They showed the watery froth of pulmonary edema, and the parenchyma had scattered patches of hemorrhages in all lobes. Microscopically, the alveoli were distended with blood and were filled with hemosideran-laden macrophages (Figure 3). Fibrin exudation and a necrotizing alveolitis were prominent. The reticulum stain showed disruption and fraying of the alveolar septa.

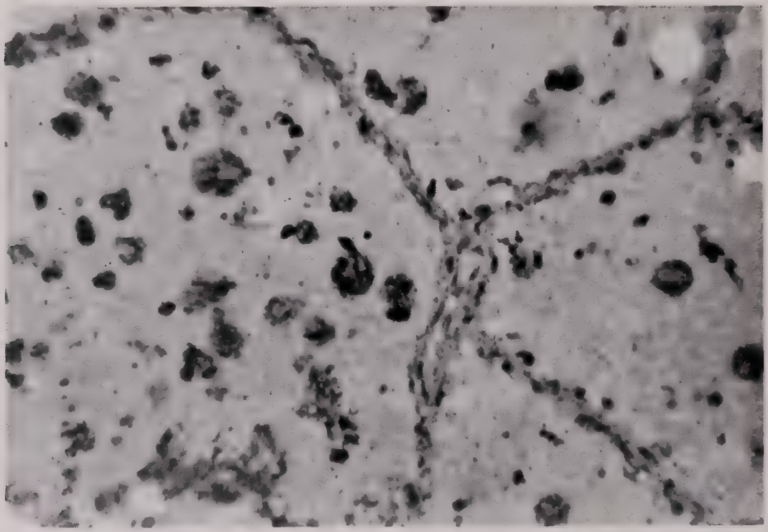

Fig. 3 — High power view of lung showing blood-filled alveoli and numerous hemosideran-laden macrophages.

The kidneys weighed 520 grams, were soft, flabby, and edematous and showed multiple punctate hemorrhages. The glomeruli demonstrated a subacute glomerulonephritis with epithelial crescents, fibrin thrombi, and thickening of the basement membrane (Figure 4). Multiple renal arteries and arterioles displayed a necrotizing fibrinoid degeneration with perivasculitis (Figure 5). Thrombi were present in medium-sized vessels in the renal pelvis and in a bladder vein but not in the major renal veins. A vessel in the periadrenal fat showed the typical picture of periarteritis. The splenic vessels and lung vessels were free of vasculitis.

Dr. Kolars:

May I ask one question: was there any evidence of arteritis in any other organs besides the bladder and adrenal?

---

*Pathologist, St. Barnabas Hospital.

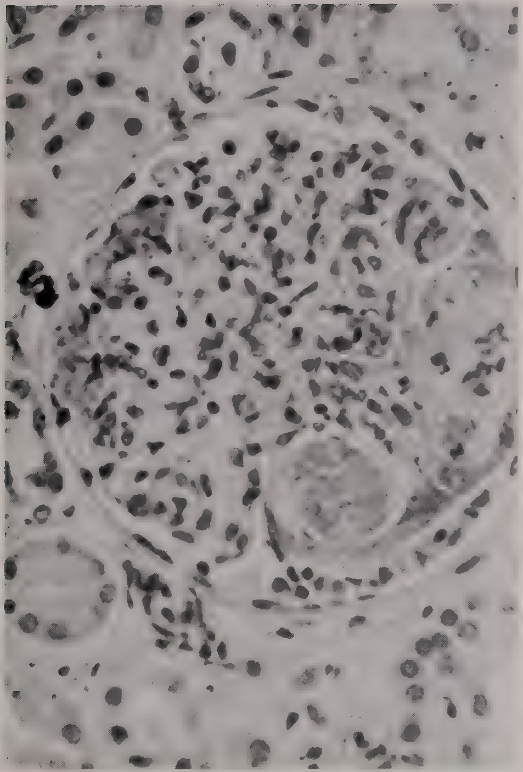

Fig. 4 — High power view of glomerulus demonstrating fibrin thrombi, cellular proliferation, and epithelial crescent formation.

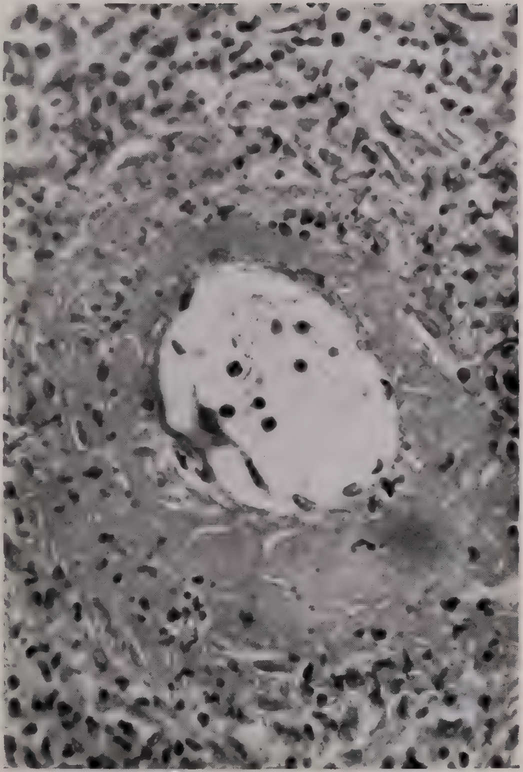

Fig. 5 — Renal vessel with smudging of wall and extensive fibrinoid necrosis.

Dr. Reece:

No, there was not. I might add that whether you call this Goodpasture's syndrome depends on how you define the syndrome. As Dr. Kolars mentioned, Ernest Goodpasture described arteritis in the splenic vessels and in vessels in the gastrointestinal tract. When Stanton and Tange rediscovered the syndrome in 1958, they said Goodpasture's syndrome was simply the combination of glomerulonephritis and pulmonary hemorrhage of obscure cause, and didn't mention the arteritis.[2] Then the ground rules were redefined and arteritis was excluded as part of the syndrome.[3] If arteritis is not part of the syndrome, Goodpasture's original case does not fit into Goodpasture's syndrome. Is this case a non-Goodpasture's syndrome, a poorpasture's syndrome, a Goodpasturoid syndrome or a Goodpasture's syndrome? I don't know, but I am going to accept Goodpasture's original case and call this case a Goodpasture's syndrome. A syndrome is supposed to be the sum of the signs and symptoms of any morbid process. This man had all the symptoms including hemoptysis and rapid fulminating death with uremia. He had a hypochromic anemia from his blood loss into his lungs, and he died within less than six months. It is true that he was not in the typical age group, but he had all of the other symptoms. As for pathological processes, he had the sum total of findings plus one — the arteritis. I think Dr. Kolars was correct. This is a Goodpasture's syndrome. But in scanning the literature, I reached the conclusion that Goodpasture's syndrome is probably just a manifestation of vasculitis, with the early changes not perceptible under the light microscope in most cases.

Continued

Dr. Kolars:

We agree that this is a muddled problem in classification and that we are dealing with a vasculitis. If Goodpasture's original case had evidence of arteritis in other organs, then I think we should attach the eponym of Goodpasture's to this case. This patient demonstrates the problems of trying to pidgeonhole diseases. This is because his case is not well understood. It is much better to accept it as a diffuse process which is expressing itself primarily in the lungs and kidneys.

Dr. Reece:

In the NEW ENGLAND MEDICAL JOURNAL there was a CPC case similar to this.[4] I like the way they summed it up. They called it an idiopathic pulmonary hemorrhage and subacute glomerulonephritis. Incidentally, we missed an important point in our discussion. Recognition of the syndrome is important because some patients can be salvaged with vigorous steroid therapy.[5]

Dr. Hay:

In just calling it pulmonary disease or chronic glomerulonephritis, you don't emphasize the underlying arteritis even if in this particular patient these were the only two organs affected. Do you think the arteritis in this particular entity is different from that seen occasionally in the intestines or other organs?

Dr. Reece:

I don't know.

Dr. Kolars:

The other curious aspect of the arteritis is that you rarely see it in the lung, isn't this right?

Dr. Reece:

Yes, and it was not present here.

Dr. Kolars:

You see it elsewhere, but you don't see it in the lung. This is one of the reasons that I think people have felt that it is a distinct entity rather than just an expression of a morbid systemic process.

Dr. Reece:

Some explain the affinity for just the lung and kidney damage on the basis of auto-immunity.[6] The lung serves as an antigen to the kidneys, initiating a hyperimmune glomerulonephritis. The similarities in the basement membranes in the alveoli and glomerulus lend some support to this concept.

Dr. Kolars:

If this were true, it would make it a distinct entity. The concept of a antigen antibody reaction in alveoli and glomeruli might also explain the response to steroids.

Final Anatomical Diagnosis

Extensive Pulmonary Hemorrhage and Subacute Glomerulonephritis (Goodpasture's Syndrome) Necrotizing Vasculitis of Periadrenal and Renal Vessels.

Richard L. Reece, M.D.
Minneapolis, Minnesota

Gulliver's Travels — Jonathan Swift

During the troubled times of the early 18th century, Jonathan Swift, who deplored the numerous foibles of the human race, wrote a brilliant and biting satire designed "to vex the world rather than divert it." Publication of the manuscript was arranged mysteriously "by the odd expedient of dropping it at the door of a publisher from the window of a hackney coach." It would seem that many of the problems which disturbed Swift continue to remain with us and, as familiarly evidenced in our own society, would be well worth a review.

Gulliver — On Decision of the Supreme Court by Precedent

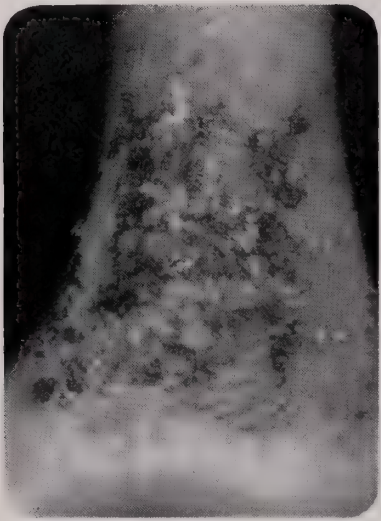
"It is a maxim among these lawyers, that whatever hath been done before may legally be done again: and therefore they take special care to record all the decisions formerly made against common justice and the general reason of mankind. These, under the name of precedents, they produce as authorities to justify the most iniquitous opinions; and the judges never fail of directing accordingly."

(To be continued)

Cabbage

Medicine has always provided an irresistible field for the activities of amateur physicians. One of the most interesting instances is the work written by Cato, the stern old Roman. He thought that cabbages were digested more easily than any other vegetable. They made a valuable tonic in vinegar. If you want to eat or drink copiously when you are invited to dinner, Cato advises you to take some cabbage in vinegar beforehand. When you have finished your repast and you want to eat again, it is sufficient to take about five leaves to have the illusion that you have not eaten for twenty-four hours. Cabbage is just as good externally as internally, being useful for trouble of the heart, liver, teeth, eyes, lungs, colic, cancer, abscess, and nasal polypi. . . . Above all, it was necessary to refrain from giving cabbages to slaves, — it made them eat too much. — Hubert Higgins: Humaniculture. Frederick Stokes Co., New York, 1906.

eczema: scourge of childhood



R. R., Age 11—Before treatment—
atopic eczema of long standing

After treatment—with ARISTOCORT
Topical Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of childhood eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings may result in systemic absorption. Appropriate precaution should be taken. When occlusive nonpermeable dressing are used, miliaria, folliculitis and pyodermas will sometime develop. Localized atrophy and striae have been reporte with the use of steroids by the occlusive technique. Whe occlusive nonpermeable dressings are used, the physicia should be aware of the hazards of suffocation and flamma bility. The safety of use on pregnant patients has not bee firmly established. Thus, do not use in large amounts or fo long periods of time on pregnant patients.

Packages: Tubes of 5 Gm. and 15 Gm.; ½ lb. jar.

Grand Rounds

Rheumatoid Arthritis in Children*

Rheumatoid arthritis is classified with the group of disorders known as the collagen diseases and, as such, presents a number of extremely difficult problems for the physician. Diagnosis is made by exclusion; prognosis cannot be stated with any certainty; there is no definitive cure for the disease, and the etiology is, as yet, unknown. To vividly illustrate how little real progress has been made in solving these problems, one has only to read Still's classic original article of 1896[1] and then survey the literature to the present to realize that rheumatoid arthritis in children remains almost as much of an enigma today as it was in Still's time. When viewed as a segment of the total arthritic population, children probably represent less than 5% of the patients;[2] however, to conclude from this that the disease rarely occurs in children would be erroneous. Available statistical data indicate that the incidence of new cases of rheumatoid arthritis is probably about 2.7 per 100,000 children under 16 years of age.[3] This figure is compared to the incidence of the nephrotic syndrome in children (2.3 per 100,000 under 10 years of age)[4] and of juvenile diabetes mellitus (less than 2.8 new cases per 100,000 under 15 years of age).[5]

Symptoms

Since by definition we are speaking of a disease which involves the joints at some time during its course, the other manifestations of what is really a systemic disease are often overlooked. Still's triad of splenomegaly, lymphadenopathy and arthritis are only three of many signs which can be characteristic, even if nonspecific, and may appear weeks or months before gross signs of arthritis appear.

Fever

Fever is very common. It may be spiking to 104 or 105 degrees or more

---

*Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, June 8, 1965.

Continued

chronic and low-grade; it may continue in spite of salicylate therapy and persist for months. During the fever the child may be restless and irritable, with a return to normal when the fever subsides. Frequently at the height of fever a characteristic rash will appear,[6] presenting as salmon-pink macules with pale centers, which spreads over the trunk but is usually concentrated on the skin overlying the joints. The rash generally disappears with the remission of the fever.

Carditis

Carditis occurs in approximately 10 to 20 per cent of cases and may be in the form of pericarditis, myocarditis, and valvular lesions with murmurs.

Subcutaneous Nodules

In the past the incidence of subcutaneous nodules in juvenile rheumatoid arthritis has been considered low.[2,7] However, recent studies[8] have described the frequent occurrence of nodules in children, which both clinically and histologically resemble the nodules of adult rheumatoid arthritis and occasionally those of rheumatic fever.

Weight Loss

Weight loss and anorexia are common and are probably manifestations of the systemic disease, as are the lymphadenopathy, splenomegaly and hepatomegaly, when present.

Joint Pain

The joint symptoms do not always begin as overt arthritis with swelling and warmth but may begin with intermittent pain in the joints in association with fever. Often the child indicates this pain by refusing to walk on an affected leg or to use an affected arm. When arthritis does finally present, it is characteristic in nature. Approximately 20%[9] of all cases will begin with a monoarticular involvement. Early in the disease there is periarticular swelling without fluid; the joint is warm but frequently not tender or red. The knee is the most commonly affected joint, the ankle and interphalangeal joints being next most common.[9-11] The cervical spine is also affected in a number of cases; Grokoest[10] found that pain and stiffness in the neck proved to be the most reliable symptom in the diagnosis of the disease.

Laboratory Findings

The laboratory tests are nonspecific and, as in the clinical findings, are of value only as part of a total picture. The most reliable, but also the most nonspecific finding, appears to be the sedimentation rate, which will be found to be greatly elevated. Most cases show a mild to moderate normocytic normochromic anemia, and in some a leukocytosis will be present. Increased C-reactive protein will sometimes be present during the acute phase of the disease. The latex fixation test shows poor reliability, being positive ony 10 to 20 per cent of the time. However, a more sensitive test for rheumatoid factor, the sheep cell agglutination inhibition test, has been more useful. In Toumbis' series,[11] in which he tested his patients for rheumatoid factor by sheep cell agglutination inhibition, sheep cell agglutination and latex fixation, the following results were obtained:

Serologic test for Rheum-factor	Number Studied	Number Positive	Per cent Positive
Sheep cell agglutination inh.	45	39	87
Sheep cell agglutination	45	18	40
Latex fixation	31	4	13

Although this is the only investigation presenting any data on the sheep cell agglutination inhibition test, the figures presented are impressive.

Therapy

Therapy in juvenile rheumatoid arthritis is really more a matter of management until such time as a remission takes place, rather than an attempt to cure the disease.

Analgesics and Anti-inflammatory Drugs

The basic therapy at present consists of analgesics and anti-inflammatory medications along with physiotherapy and psychological support. It is the usual practice to begin with salicylates in doses of 110 mgm. per kgm. per day, attempting to keep the blood salicylate level at 25 to 30 mgm%. If this fails to bring the desired symptomatic relief, steroids can be added and have been found effective in almost all cases.[12] Gauchat[12] reported a 50% success rate with Butazolidin, but this drug is infrequently used. Gold therapy also is still occasionally employed. However, a clinical remission is only the first step in treatment.

Physiotherapy

It is very important that a good program of physiotherapy be begun and maintained for as long as there is active disease, since mobility of the joints must be maintained in order to prevent joint deformities and flexion contractures. Although this may appear to be an insignificant part of the treatment, its real importance can be illustrated in a study by Edstrom[7] in which he showed the same therapeutic results in patients treated with bed rest and physiotherapy as in those treated with bed rest and also with salicylates, and steroids and physical therapy.

Prognosis

It is difficult to offer any kind of meaningful prognosis because of the great variability in the course of the disease. It may develop into a general systemic process, may be sustained through several complete and incomplete spontaneous remissions, may settle down to an indolent, painful arthritis with joint involvement lasting several weeks; or it may suddenly remit with complete recovery except for slight residual joint damage. In general, however, it can be stated that the prognosis appears to depend on when treatment is begun.[7,13] In Edstrom's series of 85 patients, the following results were obtained in patients treated early in their disease (one year or less):

Continued

State of Investigation	with	without	Total
	Chrysotherapy		
Recovered without defects	39 (63%)	14 (61%)	53 (62%)
Healed imperfectly	12 (19%)	4 (17%)	16 (19%)
Still progressing, crippled, dead	11 (18%)	5 (22%)	16 (19%)

Edstrom obtained similar results with patients placed on steroids early in their disease, illustrating once again the importance of instituting physiotherapy in an attempt to improve the prognosis.

Differential Diagnosis

A definitive diagnosis is most often made by exclusion and by the course of the disease.[14]

Rheumatic Fever

Rheumatic fever must be ruled out, and here differentiation may depend on the course of the disease. However, the following should be remembered: (1) rheumatic fever rarely occurs in children under five years of age; (2) the joint changes in rheumatic fever show severe pain, warmth and tenderness; and aspiration early in the disease will yield fluid; (3) the antistreptolysin titre will frequently be elevated in rheumatic fever; and (4) rheumatic fever will usually respond immediately and more completely to salicylates.

Collagen Disease

The collagen diseases, especially lupus erythematosus, must also be considered. The characteristic *lupus rash* is an important finding, and the patient may have signs of kidney involvement. The most specific tests would be the lupus erythematosus cell test and that for antinuclear antibody; but there is a certain degree of overlap between lupus and the other collagen diseases, as shown by Hall,[15] in a study of 130 patients with rheumatoid arthritis. In his series 98% had rheumatoid factor, but 13% had a positive lupus erythematosus cell test and 36% had antinuclear antibody. Dermatomyositis can present initially with joint symptoms but can usually be eliminated by electromyographic studies and the finding of an increased creatine excretion. On careful examination it will generally be found that the pain is adjacent to the joint rather than in it. *Periarteritis nodosa* can be a problem to differentiate when arthritis is the only symptom, because the vasculitis in the two diseases is similar. Leukemia can produce fever and joint pain before there is any abnormality in the peripheral blood.

Infection must always be considered. In the case of *pyogenic arthritis* the joint will show marked redness and inflammation. Diagnosis can usually be made by culture and smear of the synovial fluid.

Tuberculosis today is a rare cause of arthritis.

Occasionally, *allergy* may be the cause of arthritis and can usually be ruled out only by history. History should also rule out *trauma*. *Gout* is very infrequent in children. Reiter's syndrome* with urethritis, conjunctivitis and arthritis is also rare in children.

---

*See Reiter's Syndrome page 472.

Etiology

As with any disease process the hope for a cure for rheumatoid arthritis doubtless lies in the discovery of its etiology, and this is where the greatest amount of work is being done today. There are three basic etiological theories: (1) the disease is infectious or microbial in origin; (2) it is genetically determined; (3) it is one of the "auto-immune" disorders.

Infection

Many of the proponents of infection as the etiological agent in rheumatoid arthritis base their contention on the finding of rheumatoid factor in patients with infectious diseases. Clinically, rheumatoid arthritis in children is often an acute systemic disease with sudden onset resembling a severe infection. Positive tests for rheumatoid factor have been found in syphilis,[16] leprosy,[17] tuberculosis,[18] measles,[19] viral diseases,[20] and subacute bacterial endocarditis.[21] Svartz[22,23] has shown that injection of rats with Group B streptococci can produce rheumatoid factor. Abruzzo and Christian[24] suggest that prolonged exposure to an agent might be operative in the pathogenesis of rheumatoid arthritis. The injection of rabbits over a six-month period with a suspension of formalin-killed E. coli produced a serum factor very similar to the human rheumatoid factor.

Immunologic Mechanism

It may appear at an early age when certain immunologic mechanisms which might otherwise be implicated in the etiology or pathogenesis of this disease are grossly deficient.[9] It has also been observed that patients with agammaglobulinemia frequently suffer from a disease indistinguishable from rheumatoid arthritis, indicating that the disease can occur in patients with grossly defective immunologic responses. This would make it seem unlikely that rheumatoid factor, excessive production of antibodies of gamma-globulin, or the production of auto-antibodies is responsible for the disease.[25] It is possible that the manifestations of hypersensitivity and auto-immunity may be secondary to primary infections; this would be consistent with the "self + x" theory of Lawrence.[26] In this theory, self is the host cell and "x" some outside agent existing within the cell; eventually cells of the leukocyte series are sensitized to this antigenic complex. If this theory proves to be a satisfactory explanation for delayed hypersensitivity, the nature of "x" becomes very important; "x" may be a virus or a pleuropneumonia-like organism.

Pneumonia-like Organism

The possibility that the etiological agent may be a pleuropneumonia-like organism has been suggested, since there is a similarity of pleuropneumonia-like urethritis and arthritis to rheumatoid arthritis.[27] It has been established that a typical pneumonia is due to a pleuropneumonia-like organism. This disease is associated with the appearance in the serum of cold agglutinins which, like the rheumatoid factor, are 19s gamma-globulins.[28]

The negative findings in the search for an infecting agent cannot

Continued

be overlooked. Using modern techniques attempts have been made to isolate pleuropneumonia-like organisms from the blood, synovial fluid and other fluids from these patients without success.[28] Synovial fluid from adults with classic arthritis and from children with severe fulminating juvenile rheumatoid arthritis, and blood from children septic with juvenile rheumatoid arthritis, and with agammaglobulinemia and arthritis have been inoculated intraperitoneally, intracerebrally, intravenously and intrasynovially into mice, rats, guinea pigs, rabbits and monkeys, and by similar routes into neonatal mice, rabbits and monkeys. In no instance has disease been produced.[28,29]

Genetically Determined

The hypothesis that rheumatoid arthritis may be genetically determined stems from the numerous studies that have shown a higher incidence of rheumatoid arthritis and rheumatoid factor in relatives of rheumatoid individuals than in the general population. In a group of four surveys the incidence of rheumatoid arthritis averaged 3% (2.1 to 3.8) in parent and siblings of patients with rheumatoid arthritis and 0.9% (0.7 to 1.8) in relatives of control individuals.[30-33] Ziff[34] found that a significantly greater percentage of siblings, parents and offspring of rheumatoid individuals gave positive tests for rheumatoid factor by the inhibition method (in one group) and by a capillary tube latex fixation method (in a second group) than was observed among simultaneously tested control individuals. In the first group 20% and in the second group 14% of relatives had positive tests, whereas only 5 and 1.4% of control subjects respectively reacted similarly. Lawrence and Ball[35] reported a fourfold increase in the incidence of clinical, radiologic and serologic evidence of rheumatoid arthritis when compared to the expected frequency as seen in a control group of adults. Toumbis[11] reported similar results in the relatives of patients with juvenile rheumatoid arthritis. Serologic tests using the sensitive sheep cell agglutination inhibition test on asymptomatic relatives of patients with juvenile rheumatoid arthritis showed 18% to have a positive serologic test, which was significantly higher than in the control group.

Auto-immune Phenomena

The group of investigators favoring the theory that rheumatoid arthritis is an auto-immune phenomenon believe that the question of the rheumatoid factor must be dealt with before we can understand the disease. The great majority of their work has been in demonstrating that rheumatoid factor is most likely an antibody-like substance directed against an altered gamma-globulin. Studies with two fluorescent reactants prepared for the detection of rheumatoid factor in situ in tissue sections[36,37] showed that cells which form the rheumatoid factor are plasma cells and are an integral part of the synovial inflammatory exudate in rheumatoid arthritis and occur in lymph nodes as well. The cells which produce rheumatoid factor belong to the same family of cells which produce antibodies, therefore suggesting an antibody-like nature and function for rheumatoid factor. If this is the case, a search should be undertaken in the tissues for the provocative antigen, such as an altered human gamma-globulin. In work with guinea pigs[38] and rabbits[39] it has been shown that antibody formation was stimulated when a chemically altered gamma-globulin was reinjected. Giving further support to the theory that rheumatoid factor may be auto-antibody and that an antigen antibody complex does exist in vivo in patients with rheumatoid arthritis is the demonstration by Taylor and Sheperd[40] of the reaction between autologous serum (containing rheumatoid factor) and some component, presumably gamma-globulin, in subcutaneous nodules of patients with rheumatoid arthritis.

Comments

A great deal of work in the area of auto-immunization has been done by Grubb, who demonstrated certain variations in human gamma-globulin termed Gm.[41] He suggests that rheumatoid factor is an antibody directed against Gm and calls it an anti-Gm. He has further shown that anti-Gm reagins may occur in normal persons or in persons with other diseases, although they are significantly much more common in rheumatoid arthritis.[42] Other investigators have presented evidence that anti-Gm reagins are characterized by many of the features typical of the rheumatoid factors[43] and that the most distinguishing characteristic of rheumatoid factor compared to anti-Gm reagins is its ability to react as an antibody with its own autologous denatured gamma-globulin.[44]

One of the major points in Still's original work[1] was that while rheumatoid arthritis beginning in childhood resembles the disease in adults in many ways, several differences, such as the high incidence of systemic manifestations, the rarity of subcutaneous nodules and the difference in the joints affected, would make it appear that the disease in children is different from that in adults. In addition, the low incidence of positive serologic tests for rheumatoid factor has been cited as evidence for a difference in the diseases. However, in recent years most investigators have recognized that these differences are minor and probably evidences of maturity.

The argument presented by Toumbis[11] is quite representative of the premise that these diseases are similar and that Still's disease is more properly called juvenile rheumatoid arthritis. One of the most striking differences in children as compared to adults is the high incidence of hepatosplenomegaly and lymphadenopathy. However, this probably represents a hyperactive reticuloendothelial system in children, since such findings are frequently encountered in many diseases in children. The likelihood of this is further borne out by the fact that the severity of the disease in children with hepotosplenomegaly is not significantly greater. In the Toumbis series subcutaneous nodules were found in six subjects and histologically resembled those in adults; in no instance were the nodules present before the age of nine, and three of the children were over 12 years of age when nodules first appeared.

The most convincing evidence that adult and juvenile arthritis are similar is made through serologic testing. Using the sheep cell agglutination inhibition test Toumbis found 87% of the children in his study to show positive tests for rheumatoid factor, while only 13% were positive by the latex fixation reaction. This is doubtless due to the fact that the immune response in children is less well developed, requiring more sensitive techniques to detect the presence of rheumatoid factor.

The final evidence presented is that related to serologic testing of asymptomatic relatives of the patients with juvenile rheumatoid arthritis. The

Continued

asymptomatic relatives showed an incidence of positive serologic tests by the sheep cell agglutination inhibition method approximately four times that of the control patients, and the incidence of 18% positive results was similar to that in relatives of patients with adult rheumatoid arthritis as recorded in another study.[34]

Case Report

A 13-year-old white male was admitted to Mount Sinai Hospital for the first time on 10/13/64 with a two-month history of migratory polyarthritis of the hips, knees and shoulders and a sedimentation rate in the range of 30 mm. in one hour. He had been treated with aspirin and penicillin with some relief. The past history and review of systems were negative; the physical examination with special attention to joint examination was normal at this time. During his hospitalization the patient's temperature ranged from 99° to 101° and the sedimentation rate from 40 to 63 mm. in one hour. The EKG and serum electrophoresis were within normal limits. The antistreptolysin titre was 0 and C-reactive protein was negative. Rheumatoid factor was not found. No lupus erythematosus bodies were present. The hemoglobin 13.0, WBC 7,200 with 59 PMN, 35 lymphocytes, 4 monocytes and 2 eosinophiles. Urinalysis: Sp. Gr. 1.020, pH 7, albumin 0, glucose 0, rbc 1-4, wbc occasional and casts 0. Uric acid: 3.4 mg%, Na 143 mEq/L, Cl 105 mEq/L, K 5.2 mEq/L, Ca 9.8 mg% and P 4.1 mg%. X-rays including chest, pelvis, ankles and shoulders were all negative. A diagnosis of acute rheumatic fever with the possibility of a mild rheumatoid arthritis was made, and the patient was discharged on prophylactic penicillin and aspirin therapy.

Shortly after his return home he once again began to have recurring attacks of acute arthritis in the wrists, knees and hips. Decadron 3 mg. per day was started and symptoms subsided. As the dosage was reduced over a four-month period to 0.75 mg. every other day his joint symptoms recurred, and he was readmitted to Mt. Sinai Hospital on 3/27/65. On physical examination at this time the patient appeared cushinoid. Except for a very minimal tenderness on flexion of the knee and slight tenderness over the left hip, the physical examination was within normal limits. On this admission the temperature remained in the range of 98 to 99°, and the sedimentation rate was 47. A diagnosis of juvenile rheumatoid arthritis was made and the patient was discharged on high doses of aspirin.

The Penalty of Overweight

Corpulence may lead not only to physical disorders, but to psychological aberrations. Fat persons may find themselves rejected by others, and also find that they are handicapped in many normal activities.

— Cyril M. MacBryde, M.D. Signs & Symptoms Lippincott Co.

Evolving Concepts in Vascular Surgery*

DAVID F. HICKOK, M.D.
Minneapolis, Minnesota

THE PAST decade has produced a myriad of techniques and procedures available to the surgeon for the selection and treatment of patients with peripheral vascular disease. During the past five years, some semblance of order has been achieved, enabling the surgeon to more intelligently focus his selection and treatment with steadily increasing success rates. It is the purpose of this paper to emphasize a few of the evolving concepts.

Venous Disease

Superficial Saphenous Phlebitis

Superficial saphenous phlebitis is nonbacterial and requires no antibiotic therapy. This disease rarely, if ever, leads to pulmonary embolus, and anticoagulants are not required. In below-knee saphenous phlebitis the patient may be treated with a firm ace-wrap or elastic stocking and encouraged to walk or elevate his legs. When the phlebitis extends above the knee the patient is best treated with ligation of the saphenous vein at the saphenofemoral junction. This is accompanied by a marked decrease in pain. The amelioration of symptoms is presumably due to clotting the column of blood that is tamponading the phlebitic area. This procedure is performed with a small incision under local anesthesia. The patient may walk and go back to work. The pain usually completely resolves in forty-eight to seventy-two hours.

Deep Calf Thrombophlebitis

Deep calf thrombophlebitis is satisfactorily treated by the administration of heparin, followed by coumadin therapy. The route of administration of heparin is far less important than that it be adequately monitored. There is increasing awareness that large doses are required early in the treatment when the phlebitis is most active. In patients in whom heparin is contraindicated, superficial femoral vein ligation has proved to be a very satisfactory method of management. Patients who have emboli following adequate heparin therapy should be treated by venous ligation or plication, the level of which will be discussed later. At present the sedimentation rate is the only laboratory test of value in following the course of this disease. Coumadin therapy should be continued for three months.

Ileofemoral Thrombophlebitis

During the last ten years, the major advance in the treatment of ileofemoral thrombophlebitis has been prevention of the postphelebitic syndrome. The original procedure to remove clots from veins dates back to the work of Schepelmann in 1910.[1] Mahorner, in 1954,[2] revived interest in thrombectomy in this country.

Numerous reports are now available showing the beneficial effects of thrombectomy. The incidence of severe postphelebitic sequelae is 50% with heparin therapy alone

Continued

---

*Presented before Minneapolis Academy of Medicine, February, 1965.

and drops to 10% with thrombectomy and heparin. Pulmonary embolism occurs in 10% of patients with ileofemoral thrombophlebitis treated with heparin alone. With thrombectomy plus heparin the incidence drops to 1%. The efficacy of this procedure used early in the course of the disease continues to be well established.[1,3]

Treatment of Pulmonary Embolism

Venous Plication

Patients on heparin therapy who develop pulmonary embolism should undergo venous ligation. There has been a recent interest in venous plication, which leaves small channels available for continued blood flow and yet acts as a trap for any lethal clots. Whether a vein should be ligated or plicated remains to be determined. The single important factor is that venous interruption be performed to prevent further embolism. Inferior venacaval ligation gives almost one hundred per cent protection against further pulmonary emboli.[4] Bilateral common femoral vein ligation is accompanied by a ten per cent incidence of recurrent pulmonary emboli. It should be noted, however, that many patients who develop pulmonary emboli are extraordinarily poor operative risks due to cardiac or associated disease. Consequently, the lesser procedure may be indicated. In our own patients, persistent swelling following bilateral common femoral vein ligation or inferior venacaval ligation is seen in three and five per cent respectively.

Pulmonary Embolectomy

Since the original description by Trendelenburg[5] of pulmonary artery embolectomy, few successes and numerous failures have occurred. This has led to an interest in pulmonary artery embolectomy utilizing cardiopulmonary bypass. Successful management of acute massive pulmonary embolism rests on cardiovascular support, either by partial bypass or by immediate embolectomy, or both. Support of the failing cardiovascular system is imperative. From that point on, whether or not cardiopulmonary bypass is necessary to remove the pulmonary embolus has not been fully evaluated. There is no question but that cardiopulmonary bypass will allow a more thorough evacuation of clot from the pulmonary arteries. However, to tide the patient over the acute episode, immediate thoracotomy, with removal of the large plug of clot from either the main pulmonary artery, or from the right or left main pulmonary branches, is certainly life-saving. It should be kept in mind that a heart-lung apparatus is not imperative for a successful outcome in pulmonary embolectomy.[6,7]

Arterial Disease

Coronary Artery Disease

The diagnostic technique developed by Sone of coronary angiography is a major advance in the evaluation of coronary artery disease. This procedure, which has a low mortality, enables a much more careful evaluation of the coronary arterial tree. Typical of any dye injection studies on arteries, it is fraught with the problem that, despite anterior, lateral and oblique views, the dye may completely fill the lumen of a vessel and not show major disease that is present on one wall of the vessel. The same problem is commonly seen with aortography where the tremendous back-wall disease may not be delineated clearly, as the dye renders the aortic lumen opaque and the partially occluding back-wall disease is not seen. With any dye study the vessels always look better than they are.

Of the available procedures for persistent angina in coronary occlusive disease, endarterectomy, which is applicable in five per cent of patients with severe angina, has been followed by a high incidence of reocclusion. The procedure of endarterotomy,* which is opening the artery and putting on a vein patch without endarterectomy, as recently advocated by the Cleveland Clinic, is probably preferable. Further studies are beginning to show an increased long-term patency rate.

Vineberg has had a continuing experience with the internal mammary artery implant procedure. This procedure is applicable only to anterior-wall disease; at the present time there is no standardized procedure for posterior-wall disease. Internal mammary artery implant is performed with a sixty-four per cent good result in Vineberg's hands.[8] Vineberg recommends coronary angiography in all patients with persistent angina. Patients with occlusion of only one branch of the coronary artery are not operated upon, and time is allowed for them to develop their own collateral circulation. Patients with two arteries involved, for example, the anterior communicating and the right coronary, are advised to undergo internal mammary artery implantation in the hope of revascularizing the anterior wall of their left ventricle. Patients with three-vessel involvement or cardiac failure due to coronary artery disease are advised to undergo epicardiectomy* with removal of the serous pericardium, followed by wrapping a free graft of omentum about the heart and root of the aorta. This procedure has been successful both in animals and in humans in achieving some revascularization of the entire heart. Vineberg's results are certainly very encouraging, especially in view of the fact that medical measures have little to offer these patients at the present time. Several other procedures are being evaluated. The dissatisfaction with the presently available procedures lies in the fact that myocardial revascularization is not immediate, but rather requires up to six months or longer after operation.

---

*See Test Your Word Score Page 447.

Extracranial Cerebral Vascular Disease

It is now established that patients with intermittent symptoms due to extracranial vascular occlusive disease can be safely carried through surgery and given a prolonged survival rate, free from stroke. Patients with progressing stroke, or completed strokes, are not as good candidates for this procedure. There are several reports of marked improvement in their condition; however, statistically valid figures are, to my knowledge, lacking at the present time. The major problem in the acute stroke is that of hemorrhage into the infarcted brain upon revascularization of the infarcted area. This occurs in approximately fifty per cent of acute strokes.

Several safety factors have been introduced into surgery on the extracranial vessels. These factors are primarily related to conduct of anesthesia as so aptly described by Wells and his associates.[9] Studies by Champ Lyons[10] suggest that general anesthesia may decrease the metabolic rate of the brain by as much as fifty per cent. Consequently, general anesthesia in and of itself may afford some protection to these patients during complete occlusion of their carotid artery. High oxygen flow using fluothane in a closed system can increase the arterial oxygen saturation to 450 mm. mercury partial pressure. Hypercarbia, created either by hypoventilation or five per cent CO_2 and oxygen, does dilate the cerebral vessels and increases cerebral blood flow by 30 to 38%. Sustained elevation of blood pressure, using vasopressors to increase the pressure over the patient's normal range, has been shown to increase the arterial pressure distal to an occlusive lesion. This increased pressure is most important in pushing blood around the circle of Willis which may have associated disease in these patients.

Patients with bilateral disease can be safely carried through surgery under hypothermia with its added protection and the utilization of intra-arterial bypasses during the time of carotid occlusion. Monitoring of jugular vein oxygen saturations during surgery, as recently described by Champ Lyons,[10] reveals that patients with a jugular vein oxygen saturation of 60% or lower should have intra-arterial bypasses inserted to prevent damaging ischemia. Such protection is unnecessary, however, if the jugular vein oxygen saturation is over 60%. Electroencephalogram monitoring likewise is efficacious in this regard and adds another method of operative monitoring that leads to increased safety for the patient. The high incidence of aneurysmal dilatation of vein patches when the jugular vein is used has led us to the use of only saphenous vein as a source of vein patches in arterial surgery. Frequently we use no patches but rely on 6-0 Tefdak or silk for closure of the arterotomy without constriction.

At the present time the problem cases are

Continued

---

*See Test Your Word Score Page 447.

those of multiple vessel involvement and acute stroke. Careful selection of cases, accompanied by the use of the protective measures mentioned above, can carry these patients through surgery successfully with an excellent chance for good results.

Patients with innominate and subclavian artery take-off problems, demonstrating the subclavian steal syndrome, may now be operated without thoracotomy by utilizing carotid to subclavian bypasses. Many of these patients are not candidates for thoracotomy, and the ability to safely increase the distal subclavian artery pressure and stop the stealing of blood from the basilar-vertebral system by a well tolerated operation within the confines of the neck is a great advantage.

Renal Artery Hypertension

Among all the hypertensives in the United States the number of patients with renal artery hypertension is approximately one to five per cent. Congenital fibromuscular hyperplasia is the lesion of choice to treat, providing it does not involve the intrarenal vessels. A renal arterotomy and onlay of a saphenous vein-patch graft carry a success rate in the range of ninety per cent. Unfortunately, only thirteen to fifteen per cent of the renal arterial lesions are due to fibromuscular hyperplasia. Patients with renal artery atherosclerosis — unilateral or bilateral, whose affected kidneys are greater than ten centimeters in length, are amenable to renal arterial reconstruction with approximately an eighty per cent success rate. This represents a considerable salvage of kidneys. The twenty per cent of renal arterial reconstruction patients who fail may still have nephrectomy. The ten per cent of patients who are not cured by reconstruction or nephrectomy usually have irreversible vascular changes in the opposite kidney. As long as 18 months after renal arterial reconstruction, however, the blood pressure may still be diminishing, as the disease in the nonaffected kidney is reversed.

The status of this field of vascular surgery is certainly at the point where all patients, with the onset of hypertension under the age of thirty-five or over the age of fifty-five, should have aortographic evaluation of their renal arteries. Twenty-five per cent of these patients will have renal artery pathology. Many patients between the ages of 35 and 55 will have renal arterial lesions. However, case selection is necessitated prior to recommending aortography in these patients. The dehydrated and rehydrated intravenous pyelogram is ninety per cent accurate in revealing renal arterial lesions; consequently, a preaortography screening test is available to all patients with hypertensive disease.

We have all seen patients who have not responded to correction of their renal arterial lesion. Likewise we have seen patients who have disease in the smaller branches of the renal artery, which is not at this time amenable to surgical correction. Case selection still exists, even though a renal artery occlusive lesion is present.

Aortic Aneurysms

The nonhypertensive relatively young patient with an aortic aneurysm is no longer a problem. The problem patients are the elderly hypertensive patients with benign nephrosclerosis and coronary arterial disease. These patients need all the protection available to carry them through surgery. Protection of the kidneys is afforded by perirenal arterial sympathetic bloc with xylocaine and the use of mannitol during the procedure to continually wash out the kidney tubules. The proximal aorta is very carefully flushed to get rid of any debris or clots which may be present prior to final insertion of the graft. If possible, correction of renal artery stenosis by bypass or endarterectomy should be done at the same time as resection of the abdominal aortic aneurysm.

In order to protect the heart from coronary insufficiency and arrythmia, the following procedures are beneficial:

1. The use of preclotted graft minimizes leakage through the graft wall following release of the aortic clamps.
2. Installation of twenty milliequivalents of sodium bicarbonate into the graft prior to the release of the aortic clamp helps alkalinize the markedly acidic blood present in the distal extremities. We have found, as Vetto

reported,[11] that the PH of iliac vein blood after forty-five minutes of aortic occlusion averages 7.1. With the use of sodium bicarbonate instilled into the graft prior to declamping, the PH of iliac vein blood is elevated to 7.3. The arteriosclerotic human heart, unlike the dog heart, is susceptible to a rapid coronary infusion with low PH blood.

3. A vasoconstricting agent instilled into the graft prior to declamping causes peripheral vasoconstriction and decreases the usual peripheral vasodilatation accompanying the hyperemic response.

4. Over-transfusion by one unit of blood prior to declamping allows for vascular bed changes and graft oozing.

Utilizing the aforementioned procedures, the average pressure change following slow release of the aortic clamp is in the range of five to ten mm. of mercury. This is in contradistinction to the 30 to 50-mm. of mercury change in pressure when these procedures are not utilized. Arrhythmias and coronary artery insufficiency leading to ischemia and infarction have not been a problem in our hands following the institution of the abovementioned procedures.

The severely emphysematous patients continue to present the greatest risk in aortic surgery. With the wide exposure necessary, accompanied by some ileus, the diaphragmatic breathers are definitely in danger of pulmonary insufficiency postoperatively. Positive pressure breathing with good tracheal toilet and bronchodilators have markedly influenced the postoperative course in these poor risk patients.

Aorto-iliac Occlusive Disease

Patients with aorto-iliac occlusive disease are on the whole approximately ten years younger than patients with femoral-popliteal arterial disease. In this younger age group it is far preferable not to place a foreign material, the status of which ten or fifteen years later would be unknown. The long-term follow-up in some series[12] shows endarterectomy to have up to a 40% incidence of recurrent atherosclerosis in the endarterectomized segment. However, a different type of endarterectomy, where the entire media is completely removed out to the adventitia, shows a high success rate in the long-term follow-up, greater than that of bypass graft and free of recurrent atherosclerosis.[13,14] Consequently, we favor endarterectomy with venous onlay patch graft in those patients who are in the fifty to sixty-year age group or younger, providing their arteries are not heavily calcified. In the older age group bypass graft is satisfactory, shortens the procedure, and is indicated when marked calcification is present.

Femoral to Femoral Bypass

The high operative risk patient with claudication or ischemic ulceration due to unilateral iliac disease, is best treated at the present time by the Vetto femoral to femoral subcutaneous bypass graft under local anesthesia. A 95% success rate can be assured with this procedure. The good leg is not jeopardized and there is no postoperative claudication in the good leg. We have used this in patients who have superficial femoral artery disease on the good side, without the good leg being threatened. There has been no incidence of claudication in the twenty-nine cases performed to date in the good leg. There has been one late occlusion. It is now widely recognized that an absent femoral pulse is usually due to iliac or aorto-iliac disease, and the common femoral artery is usually patent if the leg is viable. A good input of blood into the common femoral artery will allow ischemic ulcers to start healing and, depending on run-off, will inhibit claudication. After femoral to femoral bypass patients with superficial femoral arterial disease or disease of the tibial vessels may not go on to completely heal their ischemic ulcers; however, the creeping ischemic necrosis and pain will stop. In order to obtain complete healing of ulcers, femoral-popliteal arterial surgery may be necessary in those patients with superficial femoral artery occlusion on the bad side.

Superficial Femoral Occlusive Disease

Numerous procedures are at present available to increase flow into the popliteal artery. These include autologous vein bypass, endarterectomy with or without venous onlay patch

Continued

and dacron bypass. In the younger patients with claudication and a small segmental lesion of the superficial femoral artery, localized endarterectomy, with or without venous patch, has proved to be highly successful. In more extensive disease, bypassing the superficial femoral artery utilizing a saphenous vein graft has withstood the test of time. Unfortunately, 25% of patients do not have a suitable saphenous vein; therefore one of the other procedures must be utilized.

At the present time all patients with symptomatic aorto-iliac disease should be considered candidates for surgical relief of their symptoms. In femoral popliteal disease it is dependent to a greater extent on the activity of the patient as to whether or not claudication should be treated. The long-term follow-up results, given a well performed delicate surgical technique, are related to the run-off available from the popliteal artery and to the rate of progression of the distal occlusive process. Certainly the two bad actors are diabetes and Buerger's disease. Fifteen per cent of diabetics with claudication will have a segmental occlusive disease amenable to surgical correction; however, these same patients will have fair to inadequate run-off from the popliteal vessels and may therefore suffer from late occlusion. Patients with Buerger's disease usually present with poor run-off and would fall under the same category. As more femoral arteriograms are performed, and with care in the selection of patients, markedly increased success rates are being achieved in femoral popliteal surgery.

Arterial Emboli

The greatest advance in vascular surgery in the last few years has been the advent of the Fogarty catheters as introduced by Thomas Fogarty, University of Oregon Medical School.[15] These catheters enable the surgeon to extract more distal emboli from cutdowns on the common femoral artery, with a very high success rate. The catheters are based on the balloon principle whereby they are threaded down an artery and the balloon blown up as the catheter is extracted. The balloon teases the clot out. These catheters are of great value during vascular surgery when one occasionally encounters distal clotting at the time of proximal arterial occlusion. Formerly, a posterior tibial artery flush technique was used in order to flush a clot out of the tibial arterial tree. Now, one can pass the catheter down the anterior and posterior tibial vessels all the way to the ankle, and extract the clot in a retrograde fashion, with assurance of a patent vessel at the completion of the procedure.

At the present time these catheters are being adapted with a flexible tip for removal of venous thrombi, which should be of considerable technical aid to the vascular surgeon. We have used them in extraction of clots from the caval and iliac venous system; however, in their present state they do damage venous valves and must be used with extreme caution.

Summary

As newer techniques are adopted, some of these concepts will undergo even further change in the near future. It should be remembered, however, that there is no substitute in this field for gentle, careful, expeditious surgical technique. It is hoped that the reader may grasp some of the great strides now being made and continuing to be made in the field.

Abstracts, Briefs and Commentaries

VAGOTOMY AND PYLORECTOMY FOR ULCER

The authors state that vagotomy combined with a simple drainage procedure is now an accepted alternative to partial gastrectomy for the surgical treatment of patients with chronic duodenal ulcer. Fears that these operations would be followed by an excessive incidence of recurrent ulcer have been proven groundless. A review of the follow-up of 100 patients with chronic duodenal ulcer treated by vagotomy and gastroenterostomy showed a disproportionate number of patients with post-cibal* symptoms similar to those following a Polya-type resection. Although the incidence appeared to be less than after gastrectomy the authors felt that too many patients still had disturbing symptoms. They therefore concluded that most of these symptoms were the result of anastomosing the stomach to the jejunum; felt that the best operation to combine with vagotomy would be one that maintained normal continuity of the gastrointestinal tract; and attempted to evaluate the operations that would accomplish this: pyloroplasty, pylorectomy, and excision of the anterior half of the pyloric sphincter. The last method, described by Judd and Nagel (1927), was selected as the simplest and safest of the three methods. The authors prefer to call the operation "anterior pylorectomy" because it draws attention to the essential part of the procedure, i.e., the destruction of the pyloric sphincter, allowing the atonic stomach which follows vagotomy to empty its contents more readily. Some patients with vagotomy and gastrojejunostomy, who had post-cibal complaints, were relieved when the gastrojejunostomy was taken down and a portion of the pyloric sphincter removed.

Follow-up on 200 cases so treated now reveals that if vagus nerve division is complete there is no increase in the postoperative occurrence of duodenal ulcer and lessened post-cibal symptoms.

The operation consists of first placing fixation sutures at the upper and lower borders of the pylorus which, when tied, aid to control bleeding. An elliptical incision is then made, removing the anterior half of the pyloric sphincter and taking more of the duodenal wall if there is a tendency to narrowing. The authors' experience is that the remaining lumen is not unduly small, as postoperative emptying is adequate even with a comparatively narrow canal. After excision the opening is closed

---

Continued

transversely by two layers of chromic OO catgut. It is very important to include the mucosa in the sutures, as the mucosa will retract if not included and carefully approximated, or stenosis will eventually follow. The ulcer is not usually removed unless it is included in the excised anterior tissue.

The authors conclude that the operation is a very safe one. There have been only two deaths in 200 cases, one from pulmonary embolism and one from acute enterocolitis. Complications have been few. In their early cases two developed obstruction, probably due to narrowing, the result of retraction of the gastric and duodenal mucosa not well approximated by the sutures.

Ninety-one percent of their operations are classed as satisfactory. The success or failure of the procedure depends very largely on the completeness of the vagal section. The conclusion is that vagotomy and anterior pylorectomy is probably the best operation available for chronic duodenal ulcer.

TREATING HERPES ZOSTER

A trial of oral therapy with abitylguanide (ABOB, Smith Kline & French) in 19 herpes zoster patients over a one-year period suggests that if treatment is started early, two or three days after the appearance of vesicles and before severe nerve damage occurs, the lesions usually involute and pain ceases relatively soon. There were no apparent undesirable side effects in any of these patients.

The patients, four male and 15 female, ranged in age from twelve to seventy years; 42 per cent were sixty or older and five were in their twenties. Seven of the patients were seen one to three days after appearance of the vesicular lesions; four were seen four to five days after; six were seen seven days after; and one was seen ten days after. All but two patients complained of pain. Previous episodes of herpes zoster had been experienced by three patients in the same sites as the current one. Two of these had received antibiotics and vaccinations for small pox respectively. These did not help. The other patient had been under treatment for a year for postherpetic neuralgia.

The author presents brief histories of all 19 patients, not reviewed here. From these summaries, it appears that crust formation during ABOB treatment occurred from four to seventeen days after the vesicles first appeared. In those cases in which therapy was initiated within two or three days after the appearance of the vesicles, prior to the occurrence of nerve damage, crusts formed in four to eight days. Eruptions cleared in less than two weeks in nearly two thirds of the cases. More than three weeks were required in only one patient. Of the 17 patients who had complained of pain, 13 reported its disappearance: six within two days; seven within seven to eleven days. Of the four patients with residual pain, all were sixty years old or over. In only one of these had treatment been started early.

CHANGES IN WESTERN MEDICAL ENVIRONMENT

Although Western medicine has made great advances in recent times, its practitioners receive less gratitude and respect than was common in the past. This disparity between performance and prestige is due to a number of imbalances and difficulties, including increasing reliance on the hospital as the place for diagnosis and treatment, the tendency for medical education to focus on tests and measurements, the fragmentation of patient care into a series of exclusive specialities, the inclination of patients to receive care away from their homes and communities, the bias introduced by private and public prepayment insurance programs that pay for the care of diseases rather than patients, and, finally, the administrative policies of hospitals and clinics, which often determine who is treated and under what circumstances. Teaching hospitals and medical schools often emphasize "aspects of medical service" rather than teaching students how to provide "the care and service patients want and need." In addition, the chronic, academic complaint that patients with trivial or nonexistent illnesses misuse outpatient facilities seems to result from a clinical disinterest in and conceptual unawareness of patients with chronic, undifferentiated dysfunctions. Chronically ill patients with multiple disorders frequently become multiclinic problem-patients who never really receive adequate medical care. Because of their training and the imbalances and difficulties described above, physicians often feel insecure about developing the comprehensive diagnostic and treatment program which many patients require. To remedy this situation, it will be necessary to teach the concept of multicausal etiology, since it operates in many organic and functional illnesses. Additionally, Western medicine must re-evaluate its teaching programs in view of the actual demands made by the patients of the medical generalist.

ECTOPIC PREGNANCY

Of 905 ectopic pregnancies treated from 1942 through 1957, 882 were tubal pregnancies, 22 were secondary abdominal pregnancies, and one was an ovarian gestation. The ratio of eccyesis to live births was 1:64, the highest ratio recorded for any large series. Of the multigravid patients, 82% had been infertile for three years or longer before becoming pregnant in the tube. A previous history of pelvic inflammatory disease was found in 56% of the patients. The use of the culdoscope materially reduced diagnostic errors and permitted the treatment of many patients before the diagnosis became obvious, or even before rupture occurred. This helped to reduce the mortality rate to 1.4% in recent years. The free use of blood and antibiotics, as well as a resident staff oriented to expect eccyesis, helped to create a better prognosis for the patient with this condition.

INCOMPLETE MASTECTOMY

In some instances surgeons elect to do a simple mastectomy for carcinoma, but in so doing Holleb et al. have pointed out that a so-called simple mastectomy may be merely an incomplete removal of breast substance and nothing more than a removal of the redundant portion of the breast.

This then leaves the individual with either remaining carcinoma cells or remaining breast substance in which carcinoma can again occur.

This again brings up the controversy as to whether or not a simple mastectomy is ever indicated in carcinoma of the breast. In the mind of the reviewer it is not.

Holleb, Arthur I., Montgomery, Robert, and Farrow, Joseph H.: The Hazard of Incomplete Simple Mastectomy. Surg Gynec Obstet 121:819, 1965.

OTITIS EXTERNA

Virtually all manifestations of otitis externa are controllable by the administration of an acid alcohol, or acid alcohol-hydrocortisone, solution. This result, however, is accomplished only after thorough cleaning of the external canal. Cleaning is done painlessly with a proteolytic enzyme ointment as a debriding agent. Therapy is begun only after the external canal is clean. Complete remission of symptoms was obtained in an average of 4.4 days, without any evidence of sensitization to the preparations used.

CARCINOMA OF OVARY

In a series of 135 patients with primary ovarium carcinoma, the rate of five-year survival was 21%. Forty-seven per cent died during the first year. The stage of disease at the time of diagnosis was an important factor influencing prognosis. Treatment of most patients consisted of operation and pelvic irradiation. Of 11 recently treated patients, eight who received homogenous irradiation of 3,000 to 4,000 r. to the whole abdomen survived the first year. This new treatment showed promise for short-term palliation. Considering distribution of ovarian cancer among the various ethnic groups in Israel, there seems to be a preponderance among women of occidental origin.

SURGERY IN POLYCYTHEMIA VERA

The complications of surgery in 54 patients with polycythemia vera were studied. Postoperative complications occurred in 45% of 62 major operations. Postoperative mortality was 18%. Fifty-two per cent of complications were due to hemorrhage, 18% to thrombosis, and 14% to hemorrhage and thrombosis in the same patient. Complications were four times more frequent in uncontrolled patients than in the controlled group. Patients with short or immediate preoperative control had complicated courses five times more frequently than those with long periods of preoperative control. It is emphasized that caution should be exercised in performing elective surgery in polycythemia. When surgery is indicated, patients should be treated with myelosuppressive agents for as long a period as is required to achieve and maintain a normal blood count or, in the case of emergency procedures, by repeated phlebotomies.

Wasserman, L.: New Engl J Med 269:1226, 1963.

ECTOPIC PREGNANCY

In 200 consecutive cases of ectopic pregnancy, 95% of the patients complained of pain which was sudden, severe, and unilateral; in 19% it was associated with syncope. A history of vaginal bleeding was obtained in 75%. Ectopic pregnancy was found on the side opposite of the pain in 11 patients. One ectopic pregnancy was implanted at the site of a previous tube ligation. The pregnancy test had limited value both from the standpoint of its accuracy in this condition and the time required to obtain the results. Culdocentesis was performed in 155 patients; the accuracy of this procedure was 97%. On admission, an incorrect diagnosis was made in 53 patients (26%). Abortion, ovarian cyst, acute salpingitis, dysfunctional uterine bleeding, and appendicitis were some of the conditions which were diagnosed erroneously. Use of culdocentesis would have revealed free-flowing blood in 85% of these patients and might have crystallized the diagnosis. In seven patients a positive tap was ignored in determining the immediate management. The past history of a previous ectopic pregnancy markedly increased the possibility of a second extrauterine gestation.

ADRENAL STEROIDS IN ULCERATIVE COLITIS

Although adrenal steroids are established as an effective form of therapy of ulcerative colitis, the evidence suggests that they add a definite risk to patients undergoing colectomy. Twenty-one patients with ulcerative colitis given steroids prior to and during colectomy were studied and compared with 18 patients also undergoing colectomy but not receiving steroids. Thirteen complications were found in the steroid-treated group and two in the nontreated patients. Wound infections and small bowel perforations were the most common complications in the steroid group. These perforations deserve special attention. There were five such complications in the steroid group, two occurring through normal intestinal mucosa. None occurred in the nontreated group. The data presented suggest that adrenocortical steroids add a definite risk to patients with ulcerative colitis undergoing colectomy.

GROUND BROKEN!
NOV. 17, 1965

APACHE PLAZA MEDICAL COMPLEX

"Standing in the middle of a boomtown in the North . . . in the middle of a 'doctor-poor' area"— *Mayor James McNulty, St. Anthony Village, in a speech at the ground-breaking ceremony for Apache Plaza Medical Complex, November 17, 1965.*

You're right, Mayor McNulty. That's why Apache Corporation's Real Estate Division decided to build a medical complex at Apache Plaza.

We knew the statistics. While the five-county metropolitan area population was growing 13.8 per cent from 1960 to 1965, the population in the area served by Apache Plaza grew 47 per cent.

We knew the Apache Plaza area statistics on doctors, too—one g.p. for each 4,100 people, one ob-gyn for each 21,000 persons, and one pediatrician for each 17,000. And we knew that there weren't enough doctors—because our customers told us many times that the small medical facility we now have just wasn't big enough. We know another thing—the growth in this "boomtown" area, northeast of Minneapolis and northwest of St. Paul, is going to continue.

Doctors are needed. And Apache is going to offer doctors the finest medical facility in the Upper Midwest. So, Doctor, if you'd like to practice in boomtown, in a modern medical building with ample parking, pathology and radiology labs, essential ancillary services, and totally flexible space-planning, call or write:

Book Reviews

The worst education that teaches self-denial is better than the best that teaches everything else and not that. — J. Sterling

MENTAL RETARDATION: A HANDBOOK FOR THE PRIMARY PHYSICIAN — A Report of the American Medical Association Conference on Mental Retardation, April 9-11, 1964. A.M.A. Publication, 141 pages, price 40¢

This book substantiates the fact that such a conference of 175 persons did occur. As a primer on mental retardation it is inadequate. A careful reader could compile a list of topics about diagnosis, cause, prevention, treatment, counselling worthy of study in authoritative sources. To do this one would overlook the emotionally biased statements which load the text.

In the preface, the editorial committee states that it "undertook to combine and reconcile the reports of the 14 task forces, modifying and supplementing material where necessary and in some cases choosing between divergent views. . . ." Additionally, "We are grateful to Miss Cathy Covert who has served as editor for the proceedings of the conferences. She has participated in an experiment in medical writing with diligence, patience, perseverance, and good humor."

This suggests that the book is not a report of the conference as we are led to believe by the title. Content hews to the line of President Kennedy's Panel on Mental Retardation. Aside from the factual data which should be checked out so that reported items can be seen in proper perspective, the emotional pitch is that primary physicians should be all things to all people. Item by item, criticism would lead to more writing and reading than the report warrants.

A HISTORY OF PATHOLOGY — Esmond R. Long, M.D., Dover Publications, New York, $2.00, 188 pages.

With the republication of **A History of Pathology** in soft covers, Dover Publications continues its tradition of resuscitating medical classics. The original 1928 edition is now a collector's item. Dr. Long, still active as the Emeritus Professor of Pathology at the Henry Phipps Institute of the University of Pennsylvania, has penned a new preface and added an appendix on recent trends in Pathology.

The book is well-bound with easily readable print. In contrast to many paperbacks, the photographic plates are unusually clear. The contributions of the great men of medicine are deftly sketched. Dr. Long parades names, events, and dates before the reader without lapsing into a dull recital. When boredom threatens, he relieves the pressure with such nuggets as: ". . . the diarrhea of the short-lived consumptive, Louis XIII, was traced to tuberculous ulcers, among the first to be recorded in the royal bowels."

I was disappointed with the sketchy review of trends in pathology over the last 35 years. But modern medicine does not lend itself to succinct summary, and this does not distract from the book's value. It will prove a valuable source for physicians who seek historical perspective.

Richard L. Reece, M.D.
Minneapolis, Minnesota

THE CHEST FILM IN MASSIVE PULMONARY EMBOLISM — D. J. Torrance, Jr., M.D., Charles C. Thomas, Publishers, 74 pages.

This 73-page monograph of the American Lecture Series is explicit in words and diagrams. The excellent reproductions of the various chest roentgenographs clearly depict the abnormal x-ray findings in pulmonary embolism.

The major contribution by the author is that the "plain film" (x-ray) of the chest is often diagnostic of massive pulmonary embolism. The signs are: a) blanching of peripheral lung field, b) difference in vascular shadows of the two lungs, c) irregularity of the hilar arteries, d) "pruned" hilar artery.

There is often no pulmonary infiltrate and no history of hemoptysis. The major symptom is dyspnea accompanied by hypotension. The electrocardiogram may not demonstrate right axis or heart strain.

I found this a fascinating and easily read book. Every patient is heir to this catastrophe. Every doctor should read this book. Truly, a gem for all!

Problem of Bile Peritonitis* — Thomas H. Wallace, M.D.

Dr. Wallace presented 21 cases of generalized bile peritonitis and gave a review of the results. Seventy-five per cent of these cases followed operation. The cause of bile leakage was distributed between the slipped cystic duct ligature, common bile duct injury at operation, and leakage from common bile duct T tube site. Eleven cases presented a very insidious onset. Nine of these, 45 per cent, were post-surgical. A 55-per cent mortality indicated serious results of bile in the free peritoneal cavity. It was very impressive to note that 100 per cent of the cases which did not receive treatment in terms of correction of the cause had 100-per cent mortality.

A Laboratory Animal Study of Barium Peritonitis**

— Robert H. Westphal, M.D.

Barium sulphate, as used in x-ray studies of the gastrointestinal tract, was injected into the peritoneal cavity of dogs. Following this, various methods of attempting to remove the barium were studied. Hydrogen peroxide was found to be of no particular value as an irrigating substance since it did not remove the barium any better than a saline irrigation. As much barium as could be removed with a saline irrigation was employed, antibiotics were also given, and the author concluded that since barium became rather solidly impregnated in the fatty tissue, particularly that of the great omentum, an omentectomy was of additional aid in removal of the firmly attached barium which would not wash off.

Distal Arterial X-ray Studies in Diabetic Gangrenous States†

— Anthony J. Carnazzo, M.D.

Fifteen diabetic patients had angiographic studies to determine the status of the distal pedal vessels in extremities in which the vessels were compromised or borderline. One method of study involved giving a low spinal to prevent pain, administering a femoral arterial injection, and then making x-ray studies of the vessels of the digits of the foot and of the arterial arches so that an evaluation could be made which would assist in the decision about the level of amputation that could safely be employed. In

certain cases minimal toe and foot amputations could be made with reasonable assurance of healing when the x-ray studies indicated adequate arterial supply.

Biliary Diversion as a Means of Correction of Induced Hypercholesterolemia in Animals*

— Harry Keig, M.D.

High serum cholesterol levels were induced in dogs by a prolonged high-fat diet. The common bile duct was transected and an anastomosis made in the terminal ileum at 100, 200, and 300 cm. from the ileocecal valve. Cholesterol levels were found to be reduced in relative proportion to the length of ileal mucous membrane available for absorption of bile and cholesterol. Effective reduction of serum cholesterol was obtained in spite of continuation of the high-fat diet. The author suggests this method as a possible means of managing the problem of hypercholesterolemia.

Investigation of the Portal System Via the Umbilical Vein

— Graham Gallon, M.D.

The authors employed the method of Gonzales and Bailey to cannulate the umbilical vein as an entree to studies of the portal vein dynamics. A 5-cm. incision was made in the skin of the midline halfway between the umbilicus and zyphoid. (The umbilical vein is found in the preperitoneal fat under the transversalis fascia.) Fifty cc. of 50-per cent Hypaque was injected, and 10 serial exposures were made in 10 seconds and another at 15 seconds. In 95 per cent of patients with suspected portal hypertension the umbilical vein was found to be patent. The authors had used a polyethylene catheter left in place for two weeks while various chemical studies were done. They have not suggested this method as a replacement for splenal portography but as an additional means of safe and direct study. They obtained a visualization of the portal vein, main trunk, superior mesentery, coronary, gastroepiploic and collaterals to the portal and splenic veins. Only two contraindications to this study were cited, those of allergy to Hypaque and of renal insufficiency. Allergic reaction was excluded by a 1-cc. intravenous injection 24 hours prior to the study.

Hematomas Within the Wall of the Duodenum**

— Robert J. Freark, M.D.

Eight patients collected within a five-year period were reported. Blunt trauma was the most common cause of such hematomas. Contrast studies were usually necessary to confirm the diagnosis, after routine survey films had suggested the possibility, following the observation of a dilated stomach and possibly an obliterated rectus muscle. Blood escapes into the submucosal or subserosal space of the duodenum, and symptoms and physical findings may simulate acute appendicitis, a ruptured viscus, an abdominal tumor, or high small bowel obstruction: the history of trauma being of the essence. The average time between injury and establishment of diagnosis is 12.8 days. Contrast studies revealed the picket fence or coil spring sign and occasionally a mere trickle of barium passing through the obstructed duodenum. Simple evacuation of the hematoma was adequate surgical management in two of the cases, and in the remainder a gastroenterostomy was also added.

In the discussion Dr. Mathewson of San Francisco cited four cases, all of which required only evacuation of the hematoma for recovery. Dr. Soper of Iowa City suggested that one should be alert to this problem in the battered child syndrome.

The Redistribution of Blood After Relief of Obstructed Common Iliac Artery* — Samuel L. Kountz, M.D.

In cases of impending gangrene of one extremity an endarterectomy or bypass graft of one obstructed common iliac artery is performed. This may result in return of viability to the involved extremity, but in turn, blood is "stolen" from the aorta, its branches and in particular the opposite iliac artery, causing the leg to become ischemic. Definitive reconstructive surgery on this iliac artery restores circulation to this extremity but, in turn, "steals" blood from the mesenteric circulation, resulting in classical intestinal angina. If such a steal persists, gangrene of the intestine with death may ensue. Experiments were performed on dogs to demonstrate the shifting of blood from vascular beds in which there was more resistance to those with lesser resistance. These studies consisted of partial constriction of the superior mesenteric artery designed to simulate clinical cases. Release of the partial obstruction did not bring a full return to normal flow. However, periarterial sympathetic neurectomy did achieve a return to normal flow; and the author therefore suggested that this procedure might be of value in emergency situations in which there is massive infarction.

In clinical cases the diagnosis was proven by mesenteric and celiac arteriograms. The intestinal ischemia symptoms were relieved by nasogastric suction and abstinence from food. This therapeutic trial aided in the clinical diagnosis of mesenteric ischemia.

In the discussion, Dr. Fry of Ann Arbor, Michigan, cited 12 cases of visceral arterial insufficiency. He stated that all distal iliac insufficiencies should have an aortogram and that both iliac arteries should be studied prior to corrective treatment of the symptomatic extremity.

Popliteal Aneurysm** — Masuki Hara, M.D.

This report concerns a group of 20 patients with 29 popliteal aneurysms, 13 of whom suffered acute vascular insufficiency of the leg. Eight of these required supracondylar amputation of the involved leg, and one had a bilateral amputation. All but one were previously asymptomatic, although two were aware of a mass in the popliteal fossa. Two patients with acute thrombosis still exhibit severe ischemia of the viable extremity despite emergency operation. The results of elective aneurysmectomy and grafting were gratifying, with only one failure out of seven procedures. Three patients had been misdiagnosed and admitted to the orthopedic service; two were explored with a diagnosis of fibrosarcoma and Baker's cyst,

respectively. The author concludes that the untreated popliteal aneurysm is fraught with constant danger of an acute or chronic occlusion, and that aneurysmectomy with grafting prior to such a catastrophic episode is the recommended procedure.

Study of Changes in DNA Synthesis As An Evaluation of Tumor Cytotoxic Agents*

— Gerald O. McDonald, M. D.

Since a major problem remaining in cancer chemotherapy is the difficulty of determining which drug will produce the maximal cytotoxic effect in the tumor of an individual patient, the authors developed a method of evaluating this effect by observations of changes in DNA synthesis. The in-vivo effect of two groups of drugs on DNA synthesis was evaluated in Ehrlich ascites carcinoma maintained in CF-1 mice, the effects being observed at multiple timed intervals from one to 96 hours. The results showed excellent correlation between carcinostatic or noncarcinostatic activity of the previously determined drugs, which were then compared in quantitative fashion with changes in DNA synthesis in the cell population. The DNA molecule was appropriately tagged for observation by employment of radioactive thiamin. In clinical patients an incision biopsy was obtained from the tumor and a cell culture was exposed to radioactive thiamin. The patient was then given the cytotoxic drug, and a repeat biopsy was made with a similar comparison and subsequent evaluation of the cell activity of the tumor by measurement of the radioactive thiamin uptake as an index of the DNA synthesis. In some patients in whom the percentage of uptake increased following cytotoxic drug administration, the tumor actually accelerated.

This method of utilizing changes in DNA synthesis as a screening procedure for candidate carcinostatic drugs is suggested as a method to determine the most effective agent, and in some situations to ascertain whether a cytotoxic agent may in fact accelerate the tumor growth.

Operations Upon the Vena Cava in Prevention of Pulmonary Embolism**

— John J. Bergan, M.D.

Three vena cava operation procedures were studied over the past seven years on 34 patients. All but two of these patients had sustained recurrent pulmonary embolus while under adequate anticoagulant therapy, or were unsuitable for this type of medication. In 11 patients with a vena cava ligation, one died of proximal cava thrombosis, seven with varying degrees of edema. Four patients with postoperative edema had cutaneous ulcers due to severe venous stasis, but none was incapacitated. In 11 patients with a vena cava plication of the Spencer type, one died during surgery, four have some degree of ankle edema, and six are asymptomatic. Cavagram showed an occluded cava in six of nine patients studied, and recanalization was not seen for as late as two years following surgery. Twelve patients had a DeWeese type of vena cava filter operation wherein a grid or screen of sutures was placed across the vena cava. In 11 patients studied by cavagram all were patent; four had varying degrees of ankle edema, and eight were asymptomatic.

*Quantitative Changes in DNA Synthesis As an Indicator of Tumor Cytotoxicity. Gerald O. McDonald, M.D., Chicago, James N. McIver, M.D., Chicago, Augusto J. Llamas, M.D., Chicago, Howard H. Sky-peck, M.D., Chicago.

**Critical Comparison of Vena Cava Ligation, Plication and Filter Operation in Prevention of Pulmonary Embolism. John J. Bergan, Chicago, David W. Kinnaird, Chicago, Karl Koons, Chicago, Otto H. Trippel, Chicago.

None of the patients having either ligation, plication, or filter operation sustained a postoperative pulmonary embolism. Each of these procedures, therefore, achieved its objective of eliminating recurrent pulmonary emboli. The 15 patients with proven cava patency have had less recurrent phlebitis, edema, and stasis stigmata than the 17 patients with occluded cavae. Several of the patients, however, did have chest pain suggestive of the possibility of small pulmonary emboli in the immediate postoperative period.

The authors performed their vena cava procedures by retroperitoneal approach. However, in the discussion, Dr. DeWeese (Columbia, Missouri) prefers transperitoneal approach by a long midline incision to facilitate the more precise approach to the vena cava for that particular technique of manufacturing a suture screen, and also to permit ligation of both ovarian veins. He cites one case of death which he believed due to embolization from ovarian vein.

Dr. Moretz (Augusta) suggests the value of placing the screen or plication conveniently below the large vein, preferably a lumbar, to permit inflow directly proximal to the screen.

Management of Ligation of the Hepatic Artery*

— William M. Monafo, M.D.

This paper reports a group of 11 adults in whom the continuity of the hepatic artery was accidentally interrupted. This occurred during cholecystectomy or pancreatico-duodenal resection in four instances and once during gastrectomy, nephrectomy, and resection of hepatic artery aneurysm, respectively. There were two cases associated with operative injuries to the common bile duct. The proper hepatic artery was ligated in six, the common hepatic in three, the right in one, and the left in one. Reconstruction of the artery was performed four times — with one death. None of the seven patients in whom reconstruction was not performed survived. Hepatic infarcts were found at necropsy in all seven cases. Detailed postoperative study of hepatic function was performed in four instances. These data indicate that when death does not occur, sufficient derangement of hepatic function follows ligation of the common or proper hepatic artery even when reconstruction is performed and there may be minimal clinical illness. The serum glutamic oxaltransaminase and alkaline phosphatase are elevated. In two cases of death on the fourth day after injury, the serum glutamic oxaltransaminase rose to more than 1250 units the day before death. The author points out that the absence of liver cyanosis at the time of injury is an unreliable sign of absence of damage.

In the discussion, Dr. Jacob Berman of Indianapolis states that even in the cirrhotic patient with good collateral venous circulation, the patient cannot survive ligation of the vessel close to the liver. He further relates dog experimentation in which, even though the animals were prepared with antibiotics, all died of liver necrosis when the hepatic artery was ligated near the liver. If, however, the hepatic artery is ligated proximal to the gastroduodenal artery or near the celiac axis, all will survive.

Changes of Liver Function Associated with Acute Pancreatitis*

— Marion C. Anderson, M.D.

Acute experimental pancreatitis of varying severity was produced in dogs, and chemical determinations of various features of liver function were performed. This study revealed that with increasingly severe pancreatitis, hepatic sinusoids become distended with blood and there is marked congestion of veins and lymphatics in the periportal spaces. Hepatic function tests became progressively more abnormal as the degree of pancreatitis increased. Only two animals had elevated serum bilirubin, but all revealed other aberrations of liver function. The authors' conclusion on their experimental findings indicates that liver damage associated with pancreatitis begins with intrahepatic circulatory congestion, which may progress to hepatocellular necrosis. Depression of liver function may explain the development of jaundice in some cases of pancreatitis, as well as the toxicity which accompanies severe forms of this disease.

Transhepatic Cholangiographic Studies**

— Fred R. Plecha, M.D.

Twenty patients were evaluated by means of percutaneous transhepatic cholangiography. Seventeen were jaundiced. The extrahepatic biliary tree was visualized in 15 of the 17, and in only one of three nonjaundiced patients. X-rays clearly differentiated between hepatocellular or intrahepatic and extrahepatic obstructive jaundice. The site of obstruction was well localized. Three of these patients were spared an exploratory laparotomy because of the findings at P.T.C. The authors state that there is no practical use of the test or procedure if the jaundice has subsided over three weeks previously.

In the discussion, Dr. Large (Detroit) states that this procedure is most useful as an aid to differentiate between carcinoma of the pancreas and chronic pancreatitis. The sharply cut-off obstruction of the distal duct in carcinoma is opposed to the tapering obstruction in pancreatitis.

Dr. Hanlon (St. Louis) states that on percutaneous cholangiography several patients revealed bile leaks, some requiring laparotomy. A 1-cm. slit was observed in the parenchyma and surface in some instances. Since these observations Dr. Hanlon now employs a Rochester needle so that a polyethylene tube can be left in the liver for a period of drainage. Dr. Mathewson of San Francisco suggests the importance of aspiration after the x-ray, so that the ducts may be decompressed. He feels that his method will avoid the leakage problem.

Hostility and Disease

ALAN CHALLMAN, M.D.[*]
Minneapolis, Minnesota

THE IDEA THAT hostility is a factor in the production or aggravation of disease is certainly not new. Almost two hundred years ago John Hunter made his well known statement that his life was at the mercy of any street urchin who angered him. He is said to have died a coronary death in a fit of rage.

Derivation

The word "hostility" derives from a root that originally meant "stranger". From time immemorial the paramount question upon sighting a stranger has been "Is he friend or foe?" Over most of human history this question was far from academic—one's life might well depend on the answer. Our own uneasiness in attending a social gathering may represent the vestigial remains of this formerly vital concern; but now, since strangers we meet at parties seldom do us any bodily harm, we can take a drink or two and tranquilize the ancient anxiety.

The "friend-or-foe" alternative led the root word "host" to develop in two opposite directions—"host" meaning one who cares for or entertains strangers, and "host" also meaning "army" that "takes care" of strangers in battle. In current English we have the words "hostile", meaning unfriendly and malevolent, and the word "hostel", meaning a place providing lodging and meals for traveling strangers. We find the related words "hospital", "hospitable", "hostess", "hospitality", and "hotel" bespeaking a friendly attitude toward a friendly stranger or outsider; and another group, "hostile", "hostility", and "hostage" referring to unfriendly relationships.

To me it seems but a little step from this primordial concern about the stranger to our ever-present and seemingly basic fear and hatred of difference. Strangers are people from a different region, tribe, or village. We have developed a constitutional dislike of differences. People who disagree with our ideas we find disagreeable; people of a different religion or skin color, of different national origin, of different politics or economics; even those persons whose "subversive treachery" conflicts with our national purposes we find reason to fear and hate.

Definition

The ambiguity we sense in the etymology of the word "hostility" appears whenever we attempt to assign an exact meaning to it. Like metallic mercury it looks like one piece but fragments when we try to handle it. Sometimes hostility means simply the emotion anger; sometimes it means a personal trait of character—the proneness to take offense, feel resentment, and seek vengeance.

Since we cannot capture this term in precise definition nor get it in pure culture for analysis, we must pursue it wherever it is found in order to learn of its *uses* rather

Continued

---

[*] Delivered at Annual Symposium, Mt. Sinai Hospital, of L. E. Phillips Psychobiological Dept. on February 29, 1965.

than of its *essence*. Imprecise terms of this sort should never be wholly condemned since they can be of great value: they permit us to agree when we choose, or to disagree if we prefer; and their very vagueness permits us to explain anything we wish with them. Words can be rich or poor. The word "pi" is a poor word since it means only 3.14159+ and nothing else. The word "love" is a rich word.

Hostility is another rich word, and if we aren't careful we may find we have another "explain-all" term. To be as specific as possible, hostility can be defined as an emotion associated with attacking or destroying. An emotion is a feeling that tends to move out.

Complication

When hostility is conscious, it is perceived as some degree of anger; but it often operates outside of consciousness so that the subject is aware of the attack, but not of feeling angry. To the extent that this happens, we cannot rely upon the most conscientious reporting of a subject as to whether he is hostile or not; his denial may be actually untrue; hostility so frequently occurs in a mixture of emotions. Aside from the ambivalence regularly found in love and hate, which is tangential to my concern here, a confusing mixture of hostility and fear is more often encountered than a pure culture of either.

Evocation

Anger and fear are reactions to a threat. When the threat appears overwhelming or unmanageable, fear is experienced; when the threat appears manageable it evokes anger; and when the force and counter-force are fairly matched, a mixture of anger and fear occurs. War heroes report feeling afraid while they attack and destroy. The same situation with a slight shift in power may evoke fear now and anger at another time, as when a small boy encounters a known bully — either alone or when accompanied by his big brother. We also see instantaneous shifts from anxiety to anger in a husband's reaction to the onset of an illness in his wife, possibly because irritation is more comfortable than worry.

A threat characteristically elicits objective defense and subjective responses of fear or anger. Broad highways of interchange connect the threat-defense-attack triangle. Self-preservation operates largely around this triangle: i.e., the perception of a threat, the preparatory arousal and strengthening for the appropriate response of defense or attack, and the carrying out of the action.

As long as one visualizes only threats that are external and obvious, the evocation of hostility or fear follows lines of common-sense reasoning. As soon as one leaves this well-lit, orderly, text-book-type world for the world of actual affairs, one finds anxiety or hostility with no obvious antecedent. For the explication* of that hostility which has no obvious origin, we prefer a model which is more sophisticated though still related to the threat-defense-attack paradigm. In such cases we may say with Freud that hostility is evoked by the frustration of a need.

Identification

Sometimes it is easy to recognize and identify hostility in a human encounter or relationship, as in the case of a punch in the nose; but sometimes it is impossible, as in the case of a charitable donation intended to deprive a legitimate heir of part of his inheritance. In most instances, the idea that hostility is involved must be at best a conclusion or at worst an inference.

Objective Signs

Objective signs of hostility are often abundant, since muscles are deeply involved in (e)motional expressions. Facial expression, posture, gestures, pitch and volume of voice, tremors, actions, respiration rate and volume, heart rate and volume are objective indicators of hostility. It will be a great advance when laboratory instruments can measure, assemble, and identify these data; but for the present the human brain can outdo any scientific apparatus in speed and accuracy and must be our main reliance in identifying hostility. Fortunately the human brain is the only computer-like mechanism that can be mass produced by unskilled labor.

---

*See Test Your Word Score Page 447.

Since there is an inevitable relationship between subjective emotion and objective somatic effects, it is difficult to see how any person can question the occurrence of "physical symptoms" in emotional states unless he is prejudiced against such a conclusion.

Subjective Signs

Subjective aspects of hostility are scrutinized by an even more refined internal identification system than are objective signs. As a rule emotions are not initially recognized as emotions but rather as appropriate and inevitable attributes of the situation. They first appear in consciousness as perceptions of external events rather than as personal reactions to them. The first step is a surge of unidentified feeling, seemingly related to the event; then identification of the feeling may occur, or it may be obscured or bypassed completely. At this latter stage, the inevitability of the reaction and the predominant role of the event are implied in the commonly heard "He *made* me angry" (very uncommon is "I got angry at him"). Finally the opportunity arrives for a more or less detached consideration of the propriety of the reaction, and the advisability of displaying it or acting upon it.

Suppression

In addition to the period of anonymity of the emotion, the content of the feeling may be found on review to be reprehensible, as would a sexual feeling for a close relative; or provocative of an undesirable retaliation, as would a feeling that the boss is dishonest. In either case the feeling would be suppressed, i.e., intentionally pushed out of consciousness. Following repeated acts of suppression the process becomes automatic, as conscious intention is no longer needed when repression occurs. Both suppression and repression interfere with the subject's capacity or willingness to report his emotion to another person no matter how ready the other is to accept and forgive.

Succession

An additional confusing factor in reporting or recognizing emotion is the commonsense practice of considering the subjective feeling and objective behavior in a cause and effect sequence to each other, rather than as simultaneous manifestations of a preceding cause. Characteristically we say, "He pointed his gun at me and my heart began to pound." In such a case it would be easy to elicit the additional information that the reporting person was also afraid of being shot and not afraid of the pounding heart. In cases where no gun is pointed, and the trigger for the emotional reaction is obscure, we usually hear, "My heart began to pound and I thought I was having a heart attack." If the accompanying fear is admitted, it will

usually be reported as subsequent to and caused by the heart action. Here the subjective feeling is reported as caused by the objective manifestation. However, we generally hear the reverse, as when we say, "I cried because I was sad", or "I trembled because I was afraid". This common-sense point of view makes for untold difficulties in medical practice. It not only influences the patient's reporting, but also affects the physician's understanding, as in the mind-body controversy, and in seeing the unity in psychosomatic disease.

Intention

Once hostility is aroused by the frustration of a need it seems that it must find a mark to strike. Normally it strikes outward against the person, object, or situation considered responsible for blocking the fulfillment of the need. In unmodified form as we see it in a small child, it is expressed as a blow, a bite, or a push. The schema illustrates the interplay of these forces and reactions.

Modification

Such primitive action is impractical for adults under most circumstances; therefore the expression is modified and may come out as a verbal tirade that "breaks no bones." This, too, may be inappropriate if the offending party or spectators are deemed to have such power, or be in communication with such persons, as could make a tirade dangerous. The hostility is then suppressed or repressed. Such operations merely retain the feeling and result in increased tension until it is discharged.

Displaced Hostility

The hostility must still find a mark to strike. It may be "*displaced*" to strike outward at a substitute object other than the one blocking the fulfillment of the need, as in the man scolding his children for very little after a "hard day at the office." Likewise, survivors of concentration camps reported feeling little hostility toward camp officials, but were enraged at fellow inmates chosen to transmit and supervise official orders.

Sublimated Hostility

The withheld hostility may also be "*sublimated*" by engaging in sports, games, vigorous exercise and the like. Both displacement and sublimation permit a socially acceptable outward expression of the hostile feelings, and generally these mechanisms along with the direct attacks suffice to discharge the hostile tension. If the hostility is considered especially reprehensible, however, as when it is more or less continuously directed toward one's own small child, it may be denied in consciousness and the denial reinforced by "reaction formation", which consists in "spoiling" the child with indulgence, material gifts, and restrictions. These actions, though rationalized as being for the child's welfare, adequately express the hostility in disguised but crippling form.

Distortion

Not infrequently, an individual's style of life does not permit an adequate "acting out" of hostility; consequently a gradual accumulation of tension may occur, especially in individuals with inherently fiery dispositions and in those who live under exceptionally frustrating conditions.

Castigation

As undischarged hostility accumulates within the person, the mark it finds to strike at is also within the person. This is first evidenced as sharp self-criticism and may go on to produce a firmly fixed conviction of inferiority and guilt, tantamount to a continuing self-attack. In such cases the attacker is generally anonymous, and the source is attributed to the afflicted individual's "recognition of the very truth", or to his projection of "what they think".

The most dramatic and pronounced cases of internally directed hostility occur only after many years of following a containment policy and are called "anxiety reactions" and "depressions". In these conditions the patient sees himself, and is usually seen by others, as the sufferer and victim, rather than as the perpetrator. The attacking force is again not identified; yet whose is the threatening, punishing, accusing voice if it isn't the person's own? Who says, "You're dying" or "You're going crazy" to the anxiety case, or "You're no good and never were any good" to the depressed? Hostility has found its mark. Since it wasn't permitted expression it has turned inward. The fact that the victim of anxiety or neurotic depression is also the one who has been blocking the expression of the hostility implies a type of poetic justice, I suppose, in determining the direction the hostility finally takes. There must be a very large reservoir in the human breast to contain the withheld hostility, since anxiety attacks and neurotic depressions usually don't appear until the fourth decade of life, even though the policy of containment has been followed since late adolescence in most cases. This delay in the outbreak of symptoms could well be the longest incubation period found in disease. It has made for great difficulty and uncertainty in grasping the genesis of anxiety and neurotic depression.

Somatization

When suppression and repression of hostility have been used too much over too long a time, the human storage facilities appear to overflow at some point. In anxiety reaction and neurotic depression the symptomatology of the overflow remains largely in the psyche, and the soma in such cases is found remarkably free of disease. The anxiety and depression apparently serve to channel the discharge of the reservoir overflow without damage to the existing structures in the body machinery. When these painful but relatively safe channels are not opened, the energy flows outward through a bodily organ or organ system, disorganizing it functionally and structurally. A good deal of thought has gone into discovering how the choice of the particular organ is made or whether it volunteers for service. The concept of psychosomatic disease, although it is a thorny issue that requires careful handling, probably does represent a needed, though crudely shaped, bridge across the stream separating psyche from soma in our twentieth-century minds.

Reduction

One advantage in any theory of the genesis and evolution of disease is that it permits a rational approach in coping with the problem; but since it is only a theory, all irrational approaches remain available. In terms of the above theories about hostility one may set about reducing its force or its consequences by: (1) encouraging direct expression through word symbols instead of blows, and with sufficient frequency so that the hostility is expended in "nickels and dimes" instead of in dollars; (2) encouraging displacement and especially sublimations as indirect expressions; (3) encouraging the recognition *and* naming of the emotion in the sentence form "I am angry", rather than "she makes me angry". This operation both detaches the feeling a little from the situation, thereby increasing responsibility and the possibility of control, and invokes the "Rumpelstiltskin phenomenon" which magically reduces the power of a thing by finding its proper name.

Prevention

Hostility may be prevented to some extent if the specific need which is being blocked is discovered and somehow more nearly fulfilled. The simplest prototype of this operation is to remove the steely fingers from the throat of a suffocating person. If the situation is more complex, as it usually is, the preventive measures will be directed toward better fulfillment of all needs—the building up of life's satisfactions in every way possible. In neurotic patients this usually means attempting to improve performance by lowering personal standards. This is a slow, uncertain route to take and generally leads to the therapist being considered an advocate of the devil.

On the other hand, it is enhancing to the professional man's reputation in most circles if he encourages religious faith and prayer in those who seek to control everything, as do hypochondriacs, for instance. Prayer appeals through language to the supernatural force for assistance, as does worry, through the pagan rites of suffering and sacrifice. However, prayer is more comfortable and more easily discontinued when it becomes excessive.

Summation

Hostility is attacking and destroying. It is closely related to fear and to survival and cannot be completely eliminated. It is evoked

Continued

by the blockage of a need. Once evoked it must find a mark to strike. It will strike *outward,* directly at the source of frustration; be displaced upon a substitute person or object in more or less disguised fashion; or be expressed in reaction formation, which is overtly a denial, but covertly a fulfillment of the hostile intention. If long prevented from outward expression by being suppressed and repressed, it may finally strike *inward* at the person concerned, who thereupon assumes the role of hapless victim. In this case the wounds produced are known as anxiety reaction, depression, and psychosomatic disease. If any or all of this is true, a rational way to cope with these problems is proposed.

Rumpelstilzchen*

There was once upon a time a miller who was poor, but he had a beautiful daughter. He told the king he had a daughter who could spin straw into gold. The king was skeptical but told the poor miller that if his daughter could spin straw into gold he would put her in a room full of straw, and if she did not spin the straw into gold by morning she must die.

As the beautiful daughter sat in the room weeping and worrying, knowing that she could not fulfill her father's promises, a small dwarf appeared before her and asked her what she would give him if he would fulfill the promise. She offered her necklace and he spun the straw into gold.

When the king observed this he was surprised and delighted, but he was skeptical. He therefore decided that it would be necessary for her to spin straw into gold once more.

The second night the small dwarf repeated the favor when the girl offered him her gold ring. The third night she had nothing more to offer, but the dwarf extracted the promise from her that he could have her first child after she married the king, who had promised to do so if she could again spin the straw into gold.

A year later, after the child was born, the dwarf returned and demanded his reward. The king pleaded and offered numerous alternatives; but because the dwarf wanted only a live child he refused to accept anything else. Finally, however, he agreed that if the beautiful queen could identify him by his name she could keep the child.

All manner of names were suggested and a commission was appointed to search out various names, but always his answer was "No." She was allowed three days and on the third day the messenger returned stating that he had discovered no new name, but that as he was walking high in the mountain in the corner of the woods, where the fox and the hare say goodnight, he discovered a small house and before the house there was a bonfire. Around it danced a laughing small man, singing and rejoicing:

Heute back' ich, morgen brau' ich,
Ubermorgen hol' ich der Konigin ihr Kind;
Ach, wie gut ist, dass niemand weiss,
Dass ich Rumpelstilzchen heiss'!

When the queen, the next day, pronounced his name the dwarf became enraged and declared that the devil had told her. He screamed and stamped his right foot so angrily that it sank deep into the earth, where it stuck. In a fit of rage he seized his left foot with his hands and tore himself in two.

E. R. SQUIBB & SONS
presents a painting of

THE UNIVERSITY of MINNESOTA MEDICAL SCHOOL

...where medical students once invaded the Campus...and brought exciting and auspicious changes.

The official move by the College of Medicine and Surgery at the University of Minnesota to its new quarters on the campus in 1893 was a memorable occasion. It was memorable not only for the "Medics" as the medical students were known, but also for the placid "Academics" who were the student body of the rest of the University. For a short time, there was the natural and expected excitement that the young medical school was to have a permanent home. Much more lasting was the awesome presence of the hard working, ambitious, critical, outspoken medical students whose pranks were a constant source of dread. The Academics and their professors alike were powerless to escape the effects of these daily pastimes; the concealment of animals, dead or alive, large or small, in desks or under the seats; intentional 'fixing' of chemical solutions so that reactions would not work, and the silence or even small riots that greeted unappreciated lecturers.

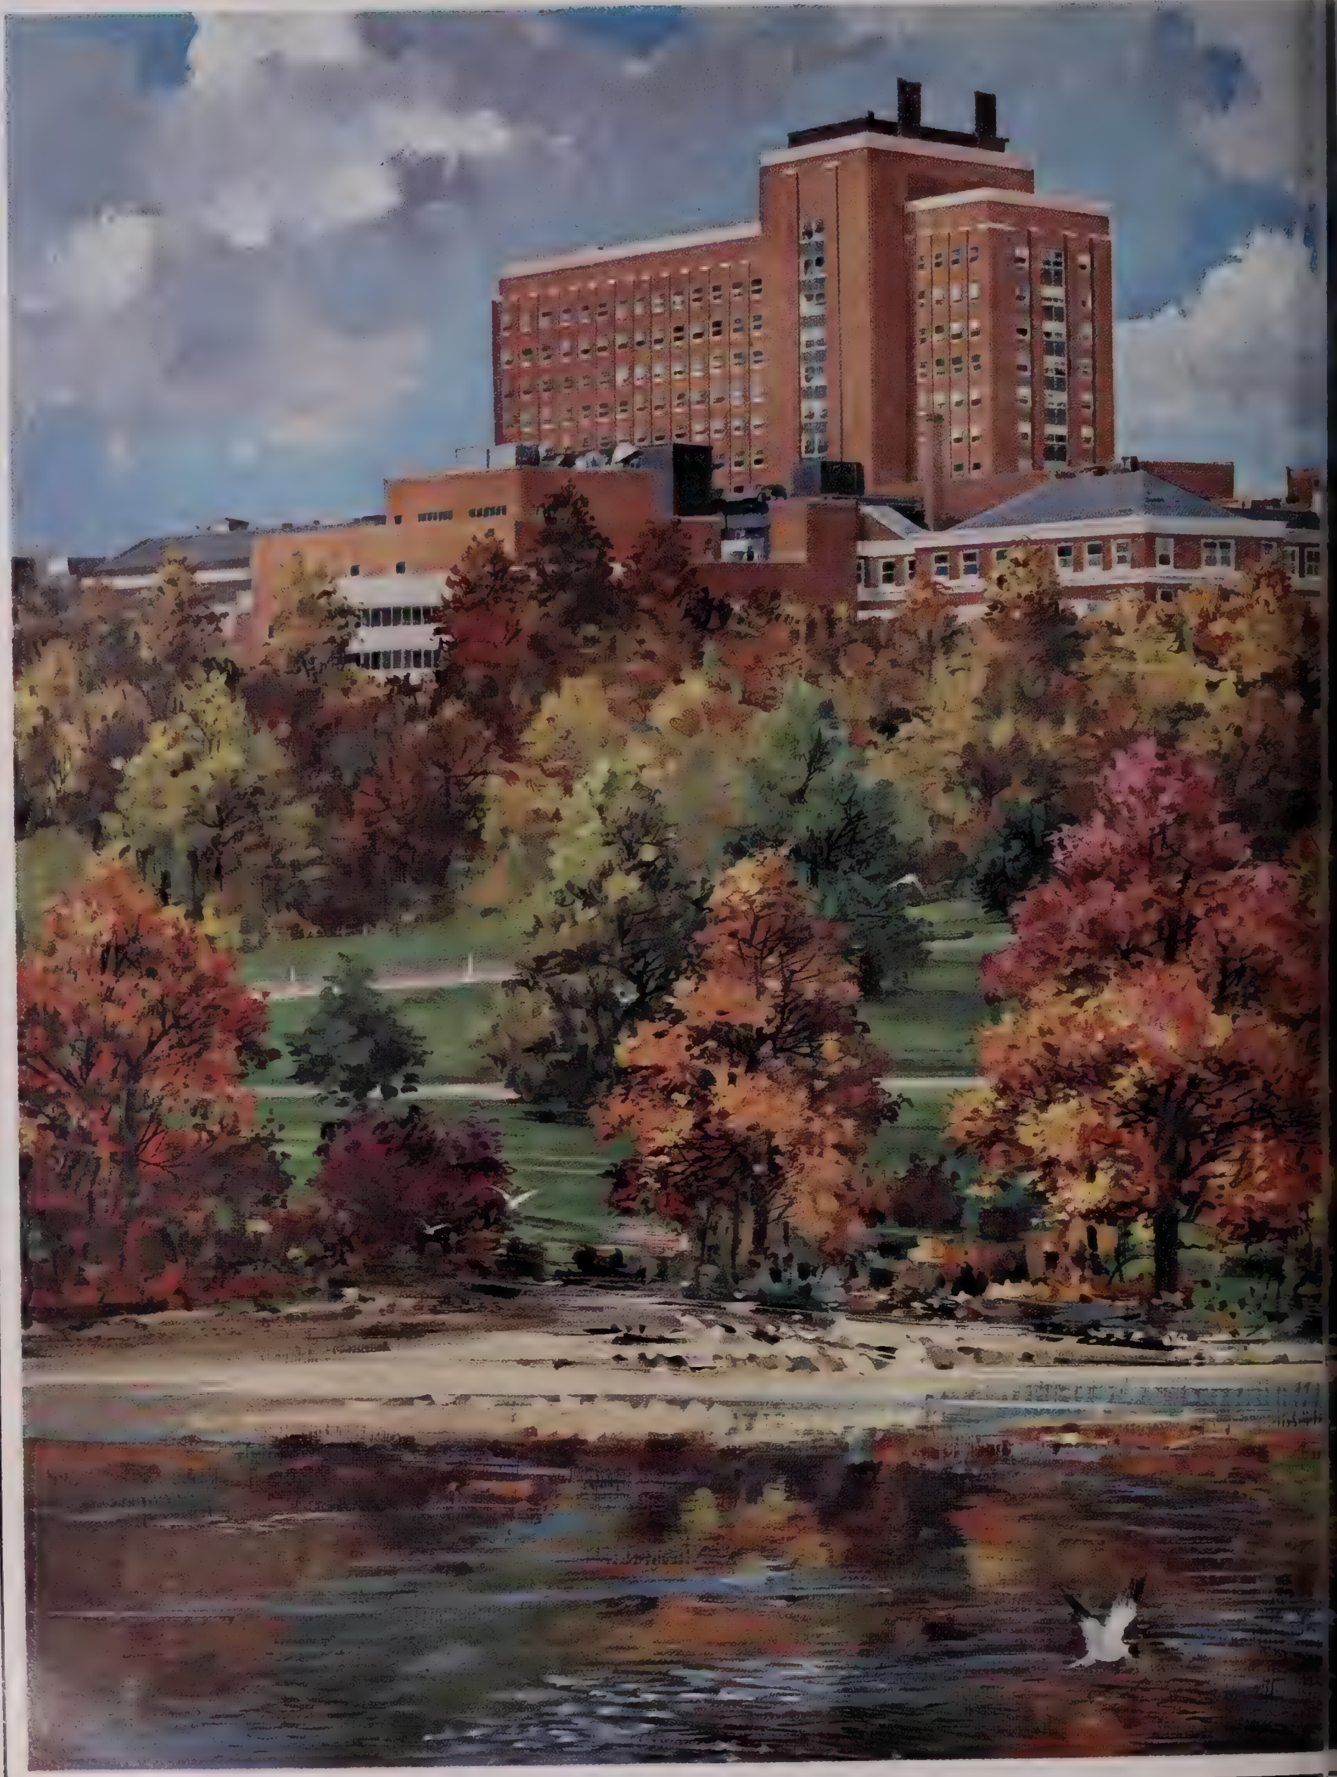
Such a tumultuous beginning strongly suggested that the future activities of the medical school would have profound and far reaching effects on the University of Minnesota. It predicted the remarkable growth of a distinguished college of medicine . . . a promise which has been realized fully.

The many contributions of the school have enriched not only the lives of Minnesotans, but people the world over. And, in all, the years of wise leadership, foresight and sometimes painful development provides a heritage for future excellence for the University of Minnesota School of Medicine.

(See overleaf)

The House of Squibb, *for over 100 years, has dedicated its fullest measure of service to the progress of medical science. This past century has provided us an admirable history in development of tools for the physician. On our foundation in the limitless field of research will be built our future contributions.*

In recalling each forward step, E. R. Squibb & Sons is aware that the challenges of modern medicine could never have been met without the tireless efforts of those men who are products of America's fine medical schools. It is in tribute to these great centers of medical education that we have dedicated the Collegia Medica program.



The impressive complex of buildings comprising the University of Minnesota Medical School is reproduced here from an original painting by John C. Berkey. The painting was commissioned by E. R. Squibb & Sons as part of the Collegia Medica program, and presented to the University of Minnesota Medical School in March, 1966. Full color reproductions suitable for framing are being sent to each graduate and made available to each student of the school.

MINNESOTA
CENTENNIAL SHOWBOAT

SQUIBB Squibb Quality — the Priceless Ingredient

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered for prolonged sitting at desks, pianos, typewriters and drafting boards. The stresses set up by the heavy, forward-tilted head and trunk, balanced precariously on an insufficient base, result in strain of the dorsal musculature, particularly at the low lumbar level.

The unusual muscle-relaxant and analgesic properties of 'Soma' make it especially useful in the treatment of low back sprains and strains. 'Soma' is widely prescribed ☐ **to relieve pain** ☐ **to relax muscles** ☐ **to restore mobility.**

Indications: 'Soma' is useful for management of muscle spasm, pain, and stiffness in a variety of inflammatory, traumatic, and degenerative musculoskeletal conditions. It also may act to normalize motor activity in certain neurologic disturbances.

Contraindications: Allergic or idiosyncratic reactions to carisoprodol.

Precautions: 'Soma', like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g., meprobamate.

Side Effects: The only side effect reported with any frequency is sleepiness, usually on higher than recommended doses. An occasional patient may not tolerate carisoprodol because of an individual reaction, such as a sensation of weakness. Other rarely observed reactions have included dizziness, ataxia, tremor, agitation, irritability, headache, increase in eosinophil count, flushing of face, and gastrointestinal symptoms.

One instance each of pancytopenia and leukopenia, occurring when carisoprodol was administered with other drugs, has been reported, as has an instance of fixed drug eruption with carisoprodol and subsequent cross reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. In cases of allergic or hypersensitivity reactions, carisoprodol should be discontinued and appropriate therapy initiated. Suicidal attempts may produce coma and/or mild shock and respiratory depression.

Dosage: Usual adult dose is one 350 mg. tablet three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white tablets and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

for the relief of low back sprains and strains

History of Medicine

Rudolf Ludwig Karl Virchow

(1821-1902)
"Omnis Cellula E Cellula"

Part II*

Invited to Wurzburg to assume the chair of pathological anatomy, he spent seven productive years there. Lecturing and demonstrating at his specially made desk in the Wurzburg Krankenhaus, the tiny, fiery professor used microscopes to convince students that cells reproduced from other cells, and taught that disease results from disturbance of cells by injury or irritants.

Due to his accomplishment in Wurzburg, he was invited to return to Berlin to become Professor Ordinarius of Pathology. Virchow accepted with the proviso that the government build him a new pathologic institute. Soon after assuming this position, he published his greatest work. Die CELLULARPATHOLOGIE fixed the minds of medical men on the consideration of diseases almost exclusively as an anatomical disorder of organs and cells. "He proceeded to rebuild pathology on his true conception of the human body as an organized cell state, a social system of continuous development, in which each microscopic unit performed its part. All fields of pathology were cleared by the new knowledge. Inflammation, tumor growth, degenerations, etc., were to be thought of now in their cellular relations, and in each of these fields Virchow himself led the way in bringing about the change. . . We are all cellular pathologists today, taking our post-Virchovian cellular sense for granted."[5]

His second love, politics, claimed attention and in 1861 he became a member of the municipal council. He also devoted much time during this period to army sanitation. He was nearly sixty when he entered the Reichstag in 1880. "The number of his public activities was almost beyond belief, most of them, including those in the Berlin city council and parliament, had a background in his comprehensive knowledge of the various medical sciences; he made application of them whenever the necessity arose."[6]

At the age of seventy-four the mellowed scholar dominated German medicine. He continued to lecture at the Institute. "The afternoon lectures scheduled in the university catalogue to last forty-five minutes were really of varying and uncertain length, for the master, wandering in the boundless field of his knowledge and experience, could never quite conform to a limit set by a clock until the present discussion had been completed in every detail. . . A part of almost every lecture was given over to a consideration of etymology; so profound a scholar of the classical languages was he as to be always able to explain and justify a terminology often at variance with current usage. One came to feel that these discourses were a source of liberal education along more lines than one.

Every man who heard the lectures on general pathology, during which specimen jars were passed, will recall with a smile the caustic protest which escaped that master of invective whenever a thoughtless student (German

Continued

usually) tilted the container until preserving fluid touched glue that held on the lid. The luckless one at once was favored with certain and always the same A. B. C.'s that underlie the solubility of glue while a hundred delighted eavesdroppers endeavored to keep their own emotion within reasonable bounds, and why not, said those who realized that for forty years the lecturer himself had with his own hands been gluing on those covers by the thousands and pasting the labels which bore his own precise inscriptions."[7] By 1886 his collected specimens had reached the huge number of approximately 17,000.

"His professional activities continued unabated until his eightieth birthday found him still in full possession of all his faculties, able to appreciate and enjoy to the full a national holiday in his honor, official testimonials from governments or scientific societies of every land in which medicine is taught and the great gold medal of science from the Kaiser himself."[8]

The theory of pathology was given great impetus by Virchow during his lifetime, and although he made many other discoveries not only in pathology but also in anthropology and archaeology, it is by his cellular pathology that his name will live.

Etymologically Speaking

Drug — from Low German droge vate (dry casks) in which droge (dry) was wrongly taken to be a designation of the contents. (Webster)

The word "drug" means something that is dried to be kept for future use. The term came to be limited to the dried herbs that were gathered for the cure of disease. After a time its meaning was extended to include minerals and animal products that were thought to have a curative effect, corresponding to that of the dried plants. The development of the significance of the word did not end there. Probably the most interesting reflection for us on the word "drug" is to be found in the use of it to indicate something that has lost its value and is no longer salable. We say that things are "a drug on the market" when nobody wants to buy them. Evidently this usage came from the fact that so many materials, which for a time had had a great vogue and abundant sale because they were thought to produce wonderful curative effects, failed after a time to do any good and thus became quite literally "drugs on the market." This is etymology's rather pessimistic bit of humor with regard to drugs and their rise and fall in popularity and vendibility.

— James Walsh, M.D., Ph.D., Sc.D.: Cures, 1924.

Character is like a tree and reputation like its shadow. The shadow is what we think of it; the tree is the real thing. — Lincoln

A gentleman will not insult me, and no man not a gentleman can insult me.
— Frederick Douglas

Meetings and Announcements

There is no dispute managed without passion, and yet there is scarce a dispute worth a passion. — Sherlock

MARCH

Minnesota Society of Anesthesiologists annual business meeting, March 11, Minneapolis. Plans to be announced. Contact: V. S. Lawrence, M.D. 330-3997.

New York Academy of Sciences conference on "Pediatric and Adolescent Gynecology, March 24-26, Waldorf-Astoria, New York. Contact Warren R. Lang, M.D., 1025 Walnut Street, Philadelphia.

Department of Otolaryngology of the University of Illinois postgraduate course in laryngology and bronchoesophagology, March 21-April 2. Write: College of Medicine, University of Illinois, Postoffice Box 6998, Chicago.

American Medical Association Air Pollution Medical Research Conference, Los Angeles, Ambassador Hotel, March 2-4. Contact AMA Office.

St. Louis County Medical Society meeting March 10, 8:00 p.m. St. Mary's Hospital, Duluth. Executive Committee Meeting at 6:00 p.m.

Twin City Urological Society Meeting, March 18, 6:00 p.m., Town and Country Club, St. Paul.

Ramsey County Medical Society Meeting, March 28, 8:00 p.m., 1500 Lowry Medical Arts Building, St. Paul.

Hennepin County Medical Society meeting, March 7, 6:00 p.m., Pick-Nicollet Hotel, Minneapolis.

Hennepin County Psychiatric Society meeting to be held in connection with the Hennepin County Medical Society meeting.

Minnesota Academy of Medicine meeting, March 9, 6:30 p.m., Town and Country Club, St. Paul.

APRIL

Minnesota Academy of General Practice meeting of House of Delegates, Hotel Radisson in Minneapolis, April 12, and annual refresher on April 13-14.

Minnesota Academy of Medicine meeting, Town & Country Club, St. Paul at 6:30 p.m., April 13.

St. Louis County Medical Society executive committee meeting, 6:00 p.m. regular meeting, 8:00 p.m., St. Luke's Hospital, Duluth, April 14.

Twin City Urological Society meeting, Town & Country Club, St. Paul, 6:00 p.m., April 15.

Ramsey County Medical Society meeting, 1500 Lowry Medical Arts Building, St. Paul, 8:00, April 25.

ANNOUNCEMENTS

Dr. Birger Strandell, a member of the faculty of the Caroline Institute, Stockholm, and editor of ACTA MEDICA SCANDINAVICA, will lecture on "Linnaeus" at Rochester, May 10, 1966. The lecture, sponsored by the Mayo Foundation chapter of Sigma XI, will be held a day before the opening of the annual meeting of the American Association for the History of Medicine. Contact: Thomas E. Keys, 200 First Street Southwest, Rochester, Minnesota.

* * *

The twenty-ninth annual meeting of The New Orleans Graduate Medical Assembly will be held March 7, 8, 9 and 10, 1966, headquarters at The Roosevelt Hotel. Presentations will be of interest to both specialists and general practitioners. This program is acceptable for twenty-nine (29) accredited hours by the American Academy of General Practice, Write Secretary, New Orleans Graduate Medical Assembly, 1430 Tulane Avenue, Room 1528, New Orleans, Louisiana 70112.

* * *

Mayo Clinic and Mayo Foundation clinical reviews, March 28-30 and April 4-6, Mayo Civic Auditorium, Rochester, Minnesota. Limited attendance. Contact: M. G. Brataas, Mayo Clinic, Rochester.

* * *

A symposium on Liver Disease will be held in the Mayo Auditorium of the University of Minnesota May 23, 24 and 25, in honor of Cecil James Watson, M.D. Symposium is open to all physicians at no charge.

* * *

Spring Cardiopulmonary Seminar will be held at Mount Sinai Hospital, May 19, 20. Contact: Jerome T. Grismer, M.D., Mt. Sinai Hospital, Minneapolis.

* * *

Minnesota State Medical Association Meeting, May 16-17, St. Paul Hotel, St. Paul. Contact: Harold W. Brunn, Executive Secretary, 496 Lowry Medical Arts Building, St. Paul.

now...introducing a **new** high-strength dosage form

SIGNEM

A 'MAXIMUM SECURITY' ANTIBIOTIC*

* THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE
long established as the broad-spectrum agent of first choice in a wide variety of infections

* WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT
triacetyloleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline

* ESPECIALLY VALUABLE IN U.R.I.
provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered

* NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY
Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN® 375

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.

Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug. Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

319 South 4th Street • St. Louis, Missouri 63102

DEPROL®

meprobamate 400 mg. +
benactyzine hydrochloride 1 mg.

Indications: 'Deprol' is useful in the management of depression, both acute (reactive) and chronic. It is particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination. It is also useful for management of depression and associated anxiety accompanying or related to organic illnesses.

Contraindications: Benactyzine hydrochloride is contraindicated in glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use.

Precautions: *Meprobamate*—Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Side effects associated with recommended doses of 'Deprol' have been infrequent and usually easily controlled. These have included drowsiness and occasional dizziness, headache, infrequent skin rash, dryness of mouth, gastrointestinal symptoms, paresthesias, rare instances of syncope, and one case each of severe nervousness, loss of power of concentration, and withdrawal reaction (status epilepticus) after sudden discontinuation of excessive dosage.

Benactyzine hydrochloride—Benactyzine hydrochloride, particularly in high dosage, may produce dizziness, thought-blocking, a sense of depersonalization, aggravation of anxiety or disturbance of sleep patterns, and a subjective feeling of muscle relaxation, as well as anticholinergic effects such as blurred vision, dryness of mouth, or failure of visual accommodation. Other reported side effects have included gastric distress, allergic response, ataxia, and euphoria.

Meprobamate—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Dosage: Usual starting dose, one tablet three or four times daily. May be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended even though higher doses have been used by some clinicians to control depression and in chronic psychotic patients.

Supplied: Light-pink, scored tablets, each containing meprobamate 400 mg. and benactyzine hydrochloride 1 mg.
Before prescribing, consult package circular.

Ramsey County Medical Society new officers are: **Dr. Brian McGroarty**, president, **Dr. John Earl**, president-elect, and **Dr. William Hollinshead**, secretary.

The Doctor and Literature

(Continued from page 408.)

Arrowsmith displays Lewis at the height of his creative powers. Then followed a long, slow, decline artistically and morally. Lewis divorced Grace and married Dorothy Thompson, by whom he had a son, Michael.

Incidentally, Michael Lewis appeared in St. Paul as Henry VIII in *A Man For All Seasons* in September, 1963.

Sinclair Lewis had a peculiar need for human companionship with a corresponding inability to support real human relationships. Both Grace and Dorothy wrote bitterly of him and his mistress Marcella Powers, who left him in disgust.

Sinclair Lewis lost every friend he ever had because of his boorishness and ingratitude for the many kindnesses he had received from their hands. He died alone on January tenth, 1951, in a Catholic Hospital in Rome of delirium tremens.

The genesis of his masterpiece *Arrowsmith* is interesting. Dr. Morris Fishbein introduced Lewis to Paul de Kruif, a microbiologist.

Conversation with De Kruif inspired Lewis to write a novel about a young doctor, Martin Arrowsmith, starting out as a general practitioner and developing into a reserach scientist, scorning cheap and easy success. De Kruif provided the medical and scientific information Lewis required. Doctor and novelist travelled through Europe seeking background atmosphere and character types for the novel.

After four years of intensive research and creative effort, *Arrowsmith* was published in March, 1925. It was nominated for the Pulitzer Prize, which Lewis, ever the rebel, refused on the grounds the Pulitzer Committee was trying to dictate the standards to which American writers must conform. *Arrowsmith* won world-wide critical acclaim.

> "The humanity of it outshines the science. It has a stirring epic quality. . ."

praised the *London Times*. Helen Hayes, the late Ronald Colman, and Myrna Loy, starred in the motion picture version of the novel in 1932.

The theme of the novel is the struggle of Martin Arrowsmith between being a well paid slave in the McGurk Institute and embracing a dedicated career devoted to pure research unhampered by the insistent demands for immediate results, by Doctor A. DeWitt Tubbs, director of the institute.

Martin resolves his inner struggle and conflict by leaving his wealthy second wife, Joyce, his well paid post at the McGurk Institute, to go off with his friend, Terry Wickett and devote the rest of his life to pure research.

Arrowsmith sums up his dedication to knowledge for knowledge's sake in the prayer:

> "God give me unclouded eyes and freedom from haste. God give me a quiet and relentless anger against all pretense and all work left slack and unfinished. God give me a restlessness whereby I may neither sleep or accept praise until my observed results equal my calculated results. God give me strength!"

Reverend Edward Keenan
St. Paul, Minnesota

A well-known philosopher has written: "Every man would like to be God if it were possible; some few find it difficult to admit the impossibility."

— Rev. Chester Tulga, Moody Monthly

BAMADEX
DEXTRO-AMPHETAMINE SULFATE
WITH MEPROBAMATE
SEQUELS
Sustained Release Capsules
977 619

By providing combined anorexigenic-tranquilizing action, BAMADEX SEQUELS Capsules help your nonshrinking patients to establish new patterns of eating less. The amphetamine component suppresses the appetite, while the meprobamate helps allay nervousness and tension. And for most patients, the *sustained* release of the active ingredients provides convenient one-capsule-a-day dosage.

Side Effects commonly associated with either component are possible but, to the extent these are dose-related, they should normally be mild and infrequent, since the total dosage of each component on the usual one-capsule-daily regimen is quite low. Also, the sedating effect of meprobamate and the stimulating effect of d-amphetamine sulfate tend, to some extent, to cancel each other out. Adverse effects not peculiar to either component have not been reported. Side effects associated with d-amphetamine sulfate include: insomnia, excitability, increased motor activity, confusion, anxiety, aggressiveness, increased libido, hallucinations, rebound fatigue, depression, dry mouth, anorexia, nausea, vomiting, diarrhea and increased cardiovascular reactivity. Effects associated with meprobamate include: skin rash, nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema, fever and transient leukopenia; also, very rarely, fainting spells, angioneurotic edema, bronchial spasm, hypotensive crisis, anuria, stomatitis, proctitis and anaphylaxis. Other serious effects have occurred after concomitant administration of meprobamate and other drugs. Massive overdosage may produce grave effects.

Precautions: BAMADEX SEQUELS should be given only under close supervision to patients hypersensitive to sympathomimetic drugs, with cardiovascular or coronary disease or who are severely hypertensive; to emotionally unstable persons and to epileptics. Patients should be cautioned not to drink alcoholic beverages while on the drug, and not to drive vehicles if they become drowsy. In all patients kept on the drug for long periods, the drug should be withdrawn gradually to avoid possible serious reactions.

Contraindications: Hyperexcitability, agitated prepsychotic states and a history of previous reactions to meprobamate.

Bamadex® Sequels®

d-amphetamine sulfate (15 mg.) Sustained Release Capsules
and meprobamate (300 mg.)

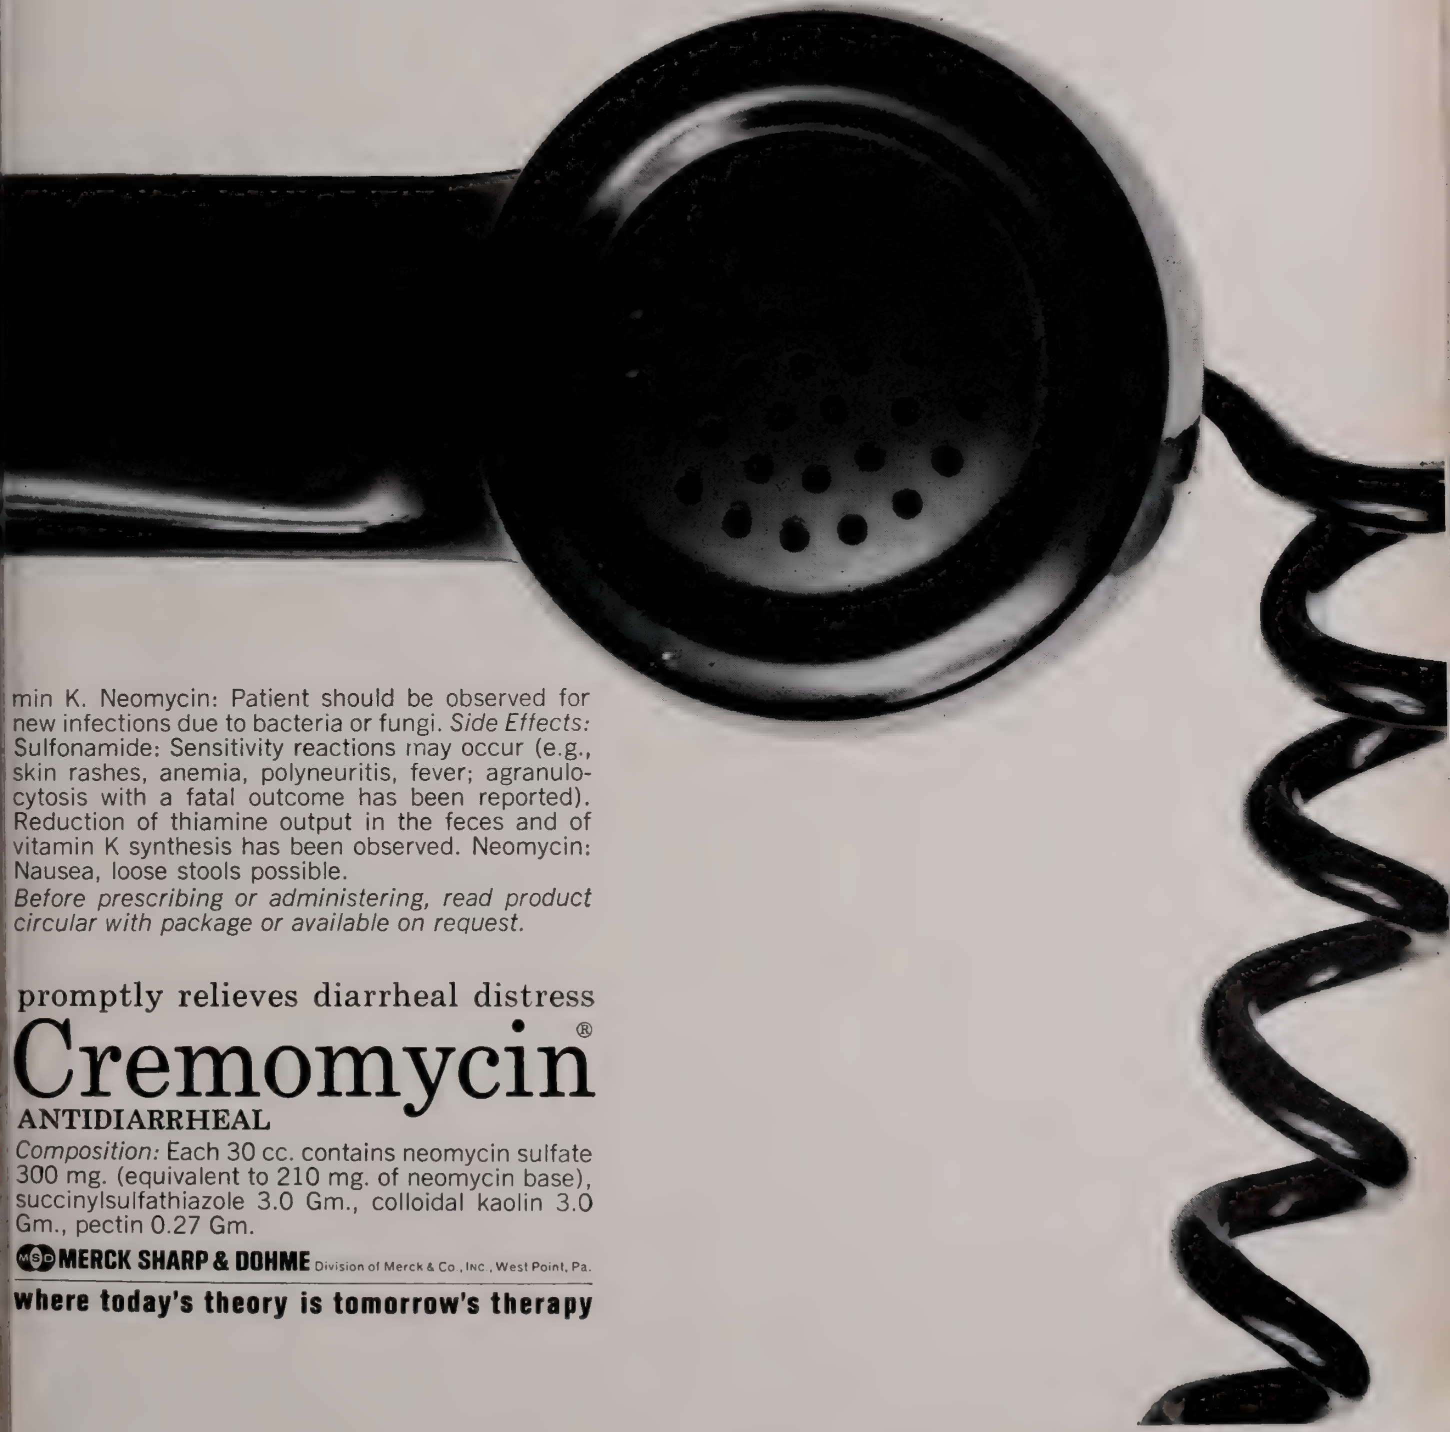
When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for
Cremomycin
can provide relief



min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.
Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress

Cremomycin®

ANTIDIARRHEAL

Composition: Each 30 cc. contains neomycin sulfate 300 mg. (equivalent to 210 mg. of neomycin base), succinylsulfathiazole 3.0 Gm., colloidal kaolin 3.0 Gm., pectin 0.27 Gm.

MSD MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

where today's theory is tomorrow's therapy

Minnesota Medicine at a Glance

The Incompetent Cervix — Stromme et al. Page 393

Incompetent cervix, an important cause of second trimester pregnancy wastage, may be of congenital or traumatic origin. Prophylactic or therapeutic cervical cerclage using the Shirodkar technique reduced pregnancy wastage from this defect from 80% to 20% in a series of 51 patients. The technique is simple and carries virtually no risk to the patient or the fetus. Delivery subsequent to cerclage may be vaginal or abdominal depending upon the type of material used.

Profunda Femoris-Popliteal Shunt — Farley et al. Page 400

There are occasions when a vein autograft or bypass procedure, which has been done to revascularize an arteriosclerotic extremity, fails and reoperation becomes necessary. In the hands of Farley et al. an alternative procedure, wherein the saphenous vein is removed and reimplanted, providing an anastomosis between the profunda femoris and the popliteal arteries avoids the previous surgical procedure by making a medial approach. They have found two advantages to this approach and have encountered no disadvantages.

Cardioversion of Ventricular Tachycardia — Aberg and Swenson Page 403

Ventricular tachycardia is a serious complication of myocardial infarction. Doctors Aberg and Swenson report four cases of ventricular tachycardia following myocardial infarction successfully treated with cardioversion.* This complication, particularly in seriously ill patients, requires immediate diagnosis and therapy. Cardioversion is suggested as the method of choice of therapy in such cases as these. In the four cases reported, all survived, with one dying subsequently, two months after discharge from the hospital.

Unusual Organism for Acute Cholecystitis — DeShazo et al. Page 409

Coagulase positive staphylococcus as a cause of acute cholecystitis is ordinarily not encountered as one of the etiologic organisms. A well documented case is herein recorded.

Brain Scanning — Wigdahl et al. Page 411

Brain scanning with radioactive isotopes, Mercury 197, is a simple, safe, highly efficient procedure to detect brain lesions, such as malignant, primary or metastatic neoplasms, non-neoplastic lesions, such as intracranial, subdural hematoma or large brain infarcts. The authors performed 432 brain scans, 338 of which were diagnostic. Of the 45 primary brain tumors encountered in this series, approximately 85% revealed a positive brain scan. About 80% of the metastatic brain tumors revealed a positive scan. Thirty positive scans of non-neoplastic lesions were encountered, one-half of which were due to cerebrovascular disease.

*See Test Your Word Score Page 447.

Ulcerative Colitis in Children — Lynn Page 417

The problem of ulcerative colitis in children, though a grave disease, need not be entirely without hope.

In the emergency treatment when the patient is in extremis the simplest possible, double-barreled ileostomy may be sufficient; but whenever it is possible, removal of the distal ileum and a portion of the colon is indicated.

When the period of election has arrived, then a permanent ileostomy and total colectomy can be planned. Before doing this it has been found to be of value to have the patient wear an ileostomy bag in order to find the most suitable place for the ileostomy, and in some instances psychiatric therapy may be indicated. In order that the patient, the referring physician, and the parents be adequately prepared both physically and emotionally, the attending surgeon should be more aggressive in explaining the value of definitive procedures in a life to be lived with a permanent ileostomy.

Predicated on his experience that ulcerative colitis beginning in childhood is very serious from every viewpoint (longevity, cancer, perforation, invalidism, etc.) the author makes a strong plea for earlier surgical extirpation accompanied by permanent ileostomy.

Cystic Dilatation of the Common Duct — Carlson and Glas Page 429

Cystic dilatation of the common duct is relatively rare but may be encountered, and it is therefore well for any surgeon to have in mind the most desirable procedure for the alleviation of the symptoms of this disease. If the diagnosis can be established, the relatively simple procedure of choledochocysto-duodenostomy, as illustrated, can be advantageously reviewed.

The Penicillins — *Medical Seminar* —
Graduate School of Medicine, Mayo Clinic Page 479

Current clinical areas of interest in penicillin therapy include the following: the development and application of the semisynthetic penicillins; the use of massive doses of penicillin G in gram-negative bacterial infections; the significance of resistant staphylococcal carriers who acquire streptococcal pharyngitis; the relative increase in resistance to penicillin G of some strains of gonococci; the use of penicillin in tetanus prophylaxis in the unimmunized person to avoid the hazards of antitoxin; the use of steroids in continuing penicillin therapy in those who manifest allergy to penicillin; the continuing problem of the nasal carrier of staphylococcus and hospital-acquired infection; and the emergence of increasing strains of sulfa-resistant meningococci, making penicillin the drug of choice in these infections.

Despite the problems of allergic reactions and resistant staphylococci, the penicillins remain drugs of great importance. After years of intensive use, penicillin G is still essentially effective against the same organisms and diseases that confronted it 25 years ago. The development of the semisynthetic penicillins has to some extent countered the problem of resistant staphylococcal infections and has broadened the mode of administration and, in some instances, the spectrum of activity of the penicillins.

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

5 MG/KG. DOSAGE IN ML.
*dosages given to closest 0.1 ml.

A RELIABLE, PROVEN PRODUCT . . .
The BSP test, introduced in 1925, remains one of the most sensitive laboratory procedures available for determining hepatic function.

A STERILE, CONVENIENT PUT-UP . . .
Each BSP Disposable Unit contains: a sterile, glass, disposable syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of Bromsulphalein.

The BSP unit is designed for maximum patient protection. The precalibrated syringe makes weight calculations unnecessary and provides for proper dosage regardless of patient-weight.

ECONOMICALLY PACKAGED . . .
Prepared for economic unit dispensing, this completely disposable put-up affords a savings in time and labor—the most costly commodities.

when pain is beyond the reach
of simple analgesics

In the management of mild to moderate pain, give your patients comprehensive relief. TRANCO-GESIC extends the range of usefulness of aspirin by dimming pain perception—and *also* reducing mental and muscle tension.

TRANCO-GESIC®
tablets
chlormezanone 100 mg. with aspirin 300 mg.

subdues the major contributors to pain:

- pain perception
- mental tension
- muscle tension-spasm

TRANCO-GESIC is so well tolerated it can be prescribed for anyone who can take aspirin. It is non-narcotic, and free from dangers of addiction, habituation, or dependence. TRANCO-GESIC is effective in all types of mild and moderate pain. Of 862 patients who were treated with chlormezanone and aspirin for various disorders, 88% reported excellent or good pain relief.[1]

Side effects have been minor. Occasionally gastric distress, weakness, sedation or dizziness occur. Reversible cholestatic jaundice has been reported on rare occasions. However, in 4,653 patients treated with chlormezanone, 97.7% had *no* side effects.[1] *Contraindication:* just one: sensitivity to aspirin. *Dosage:* Adults, usually 2 tablets three or four times daily. Children (from 5 to 12 years), 1 tablet three or four times daily.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

one mid-evening

New 300 mg tablet It's made for b.i.d.

For Adults–2 tablets provide a full 24 hours of therapy...with all the extra benefits of DECLOMYCIN...lower mg intake per day...proven potency... 1-2 days' "extra" activity to protect against relapse or secondary infection.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE
300mg FILM COATED TABLETS

Effective in a wide range of everyday infections—respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Warning — In renal impairment, usual doses may lead to excessive systemic accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of discomfort.

Precautions and Side Effects — Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. Use of demethylchlortetracycline during tooth development (last trimester of pregnancy, neonatal period and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use but has also been observed in short treatment courses. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment. Side reactions include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and dermatitis. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Anaphylactoid reactions have been reported.

Contraindication—History of hypersensitivity to demethylchlortetracycline.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products.

Capsules: 150 mg of demethylchlortetracycline HCl.

Tablets: film coated, 300 mg, 150 mg, and 75 mg of demethylchlortetracycline HCl.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York

President's Letter

Again, the time of the Annual Session of the Minnesota State Medical Association is rapidly approaching. This year, meeting in St. Paul on May 16th and 17th, a very representative clinical program has been developed, directed toward the multiple interests of Minnesota physicians, and concerned basically with an appeal, in some area, to every physician's interest.

No program can develop, in the limited time available, a stimulus to attendance at all of the varied presentations on the program, but by the incorporation in the total program of specialty groups, every physician can benefit by participation in the field of his major interest. The speakers will be highly qualified, recognized authorities and representative of medicine in the nation.

Over and above the clinical program, however, is the possibility of physician participation in the other areas in which an Association such as ours must operate. Beginning with the County Societies, and expanding to the State Association, there is always a feeling on the part of some physicians that their personal feelings about policy, procedures and official position are not properly represented by the Association. In essence, this is true of every organization, medical, political, religious or industrial. In the area of medical practice where individualists are the rule, it may be more obvious than in any other field, but the opportunity for personal expression of dissent is greater in organized medicine than in any of those other areas.

Regrettably, this opportunity is too infrequently used. Any dissension expressed in a hospital coffee shop or doctor's cloak room, any disagreement ventilated to fellow physicians, any withheld opinions which lead the holder to nonparticipation in local, county or state determination of policy, are basically an evasion of responsibility.

While it is true that policy is determined by the expressed attitude of the majority, the opinion of every member of this Association is invited, and the consideration of that opinion is never cursory, nor disregarded.

An obligation of the Association has always been a full consideration of member opinion. The attitude of the Council has always been attention to opinion, individual, group or organizational. The Council would fail in its responsibility if all viewpoints were not considered and would be derelict in duty if Council action failed to represent the consensus.

In these trying times, and at this session, the attention of every physician is directed to the opportunity to voice his opinion of the path medicine is following. The reference committees of the House of Delegates are open to all interested physicians, all of whom are encouraged, even urged, to attend and to contribute to these policy proposing hearings.

Never before in the history of medicine has there been a greater need for full physician participation in determining medical policy; never before has there been a greater need for unified physician position, and never before has there been so demanding a recognition by physicians of their strength as a group and their inherent weakness as individuals.

Present planning of this medical program includes an opportunity to hear and question a representative of the Social Security

Lost and Found

CHIHUAHUA — Lost-fem. Tan and white Reward Irving-Calif IR 8-0341

Lost

THE BITTER TASTE OF ORAL PENICILLIN.

See V-Cillin K®
for full details.

DOG found—Black Peke, female. 10-26. Lincoln Park West. 943-0794

Found

A MORE PLEASANT WAY TO TAKE ORAL PENICILLIN.

Check V-Cillin K®
for the facts.

DOG lost—Sable and white collie. Vic. 60th and Kedzie on Oct. 19. Children grieving. Any information appreciated. Reward.

Patients won't complain about bitter penicillin taste when you specify V-Cillin K. Here's why: It has a special coating, only one and a half *thousandths* of an inch thick. Because it is designed to dissolve after approximately six seconds, this barrier to bitterness remains on the tablet as it slides past the tongue. When the tablet reaches the stomach, however, the coating has dissolved, and the penicillin is ready for immediate absorption into the bloodstream.
Result? The proved efficacy of potassium penicillin V without the penalty of bitter taste.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

Office Management of Hearing Problems

JEROME A. HILGER, M.D.
St. Paul, Minnesota

EIGHTEEN MILLION AMERICANS suffer from handicapping hearing loss. The number of sufferers per thousand of population is on the increase. Only arthritis exceeds hearing handicap as a cause of chronic disability in the over-65-years age group (178 with hypacusis per thousand oldsters). The hearing handicapped, quite reasonably, expect their disability to be appreciated and, at least preliminarily, assessed by their personal physician. Intelligent evaluation is within the purview of an interested practitioner. A constructive inquiry assures the problem medical supervision rather than disposing of it to the exploitation of purely commercial or more charlatan interests.

In this most sociable world adults are readily aware of hearing loss even when only moderate. The occasional complacent victim is made well aware by his associates. Children, on the contrary, are frequently uncomplaining or oblivious to hearing impairment. Poor speech patterns, faulty reaction to sound, and school screening programs are the common identifiers of childhood hearing deficiency.

Causes of Impaired Hearing

Otoscopic examination of the patient with a hearing problem readily demonstrates a sound-obstructing mass if present in the external canal.

Retained Cerumen

A retained cerumen mass is a common and sometimes tedious problem. Manual removal with a small "loop" or spud is preferable if the patient has a known ear drumhead defect or if one is suspected from a history of chronic ear discharge. "Lytic" agents to dissolve cerumen can result in more mischief than aid because of skin irritation or canal fundus fouling. Careful irrigation with the traditional cerumen syringe or an irrigation

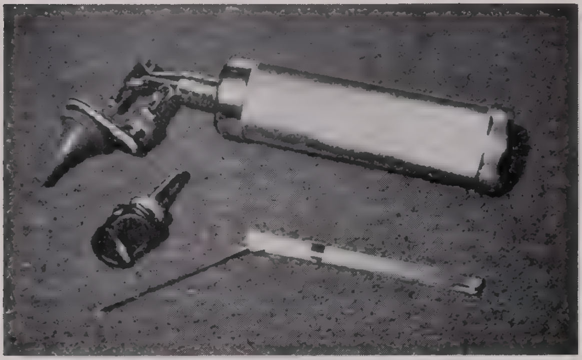

Fig. 4 — Equipment for diagnostic myringotomy.

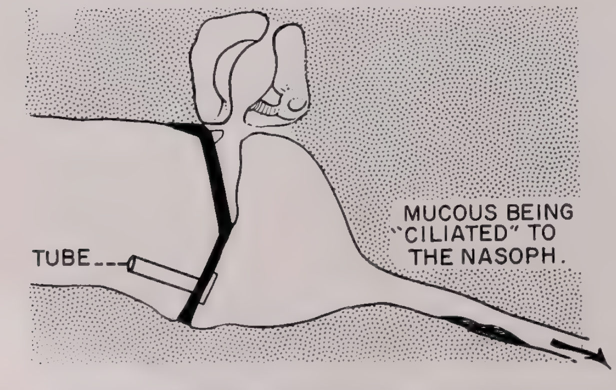

Fig. 5 — Microtube technique for assuring long term ventilation of the middle ear chamber.

bottle adapted to a compressed air source is a safe removal technique. Prior softening with hydrogen peroxide drops can be helpful in some cases. If the removal has been traumatic or if there is inflammation of the canal skin, careful drying with an aspirating tip or sterile cotton applicators can be supplemented with a light insufflation of fine boric acid powder with neomycin powder added in a strength of one part of neomycin powder to eight parts of boric acid powder.

Air Chambers of the Middle Ear

In the absence of an immediately visible cause for a hearing complaint a moment's evaluation of the patient will affirm medical interest and point the way to the pathology. Assessment of the conductive mechanism and of the air chamber of the middle ear through the intact drumhead calls for more than simple otoscopic examination. Routine test of drumhead mobility with the pneumatic speculum (Figure 1) develops skill in interpreting the aeration of the middle ear. Simple transnasal bag (Figure 2) inflation of air into the middle ear is informative. Uncertainty calls for resolution with tuning fork tests and sometimes diagnostic myringotomy.

Impaired Conductive Mechanism

The locus of hearing pathology is determinable in a practical way by the 500 cycles per second tuning fork. The function of the sound-conducting system of the external and middle ear as contrasted with the sound-perceiving system of the internal ear and central neural pathways is readily evaluated with this sound source. For the occasional examiner a simple "self-test" will refresh the principle of sound lateralization. With the vibrating fork based on his sinciput or on his central incisor teeth the examiner will, when he occludes one ear canal, note that he has "lateralized" the midline sound source to that ear. Now, when he repeats the test on his patient, he is reminded that "lateralization" of the sound to the patient's poorer ear indicates a conductive system fault in the ear (Figure 3). Similarly, when the vibrating fork is applied to the "mastoid process" at the posterosuperior pinna attachment of the impaired ear it will be heard better or nearly as well as when held to the ear canal orifice. (The normal ear hears the fork approximately twice as long through the air conduction system at the canal as through bone conduction at the mastoid.)

If then the patient lateralizes the sound from the midline fork to his poorer ear it can be reasonably assumed there is fault in the conductive system medial to the observed drumhead. If the latter is mobile and translucent, ossicular dysfunction is the probable hearing fault. By far the most common ossicular disorder is otosclerosis — a lesion of the labyrinthine capsule which can involve and immobilize the stapedial footplate. Surgery can resolve this fault once recognized.

Diagnostic Myringotomy

If, on the other hand, the drumhead is not translucent or is not mobile, diagnostic myringotomy is necessary to determine the presence or absence of middle ear fluid (Figure 4). Myringotomy in the adult is usually practicable without anesthesia if the patient is of a stable temperament. Visualization is obtained with ample light and magnification with a lens otoscope or speculum. The myringotomy blade must be sharp. The discomfort under these circumstances is transient as with a hypodermic injection. The incision with a two-edged, diamond-shaped blade into the posterior inferior drumhead quadrant will allow air bubbles into the fluid-filled middle ear chamber and fluid will be expelled with transnasal air bag insufflation, suction, or alternate pressure change with the pneumatic otoscope. Occasionally a "micro-tube" (Figure 5) of nonreactive material is placed through the drumhead to provide continuous ventilation and shorten an otherwise tedious resolution, thus precluding the necessity of repeated myringotomies. This procedure requires technical experience and excellent visualization with adequate magnification.

The adult with middle ear fluid must have careful nasopharyngeal examination. Inflammatory response to infection or allergy is the usual cause, but carcinoma in the peritubal area causes a fluid-filled middle ear as early evidence in some cases.

For the child, diagnostic myringotomy usually requires the immobility of general anesthesia. "Micro-tubes" through the drumhead are commonly used to further resolution of the reactive middle ear.

Localizing the Pathology

If the 500 cycle per second fork, vibrating on the midline skull, is lateralized to the better hearing ear and away from the poorer ear, the pathology in the poorer ear is in the sensorineural portion of the hearing system (Figure 3). In addition, in the sensorineural defective ear, if the base of the vibrating fork is applied to the mastoid process at the posterosuperior pinna attachment, it will be heard less well than when held at the canal orifice. Preliminary to testing his hearing-impaired patient, the occasional examiner is again well advised to refresh in his mind this relationship by testing his own ear with and without canal occlusion.

A Spectrum of Tuning Forks

When both ears have significant hearing loss, additional tests are definitive. Tests can be quantitative as well as qualitative. Preliminary study of "how much" loss is present can be approximate. Speech tests by whisper techniques have many faults. A watch test by simple distance measurement is unimpressive but gives some useful information when properly compared with a normal. The threshold vibrations of a spectrum of tuning forks (500 and 2000 are key frequencies), when compared with a normal hearing ear, are informative even in uniform ambient room noise. A basic pure tone air conduction audiometer with properly occlusive ear muff receivers provides a better quantitative method for a general diagnostic clinic given

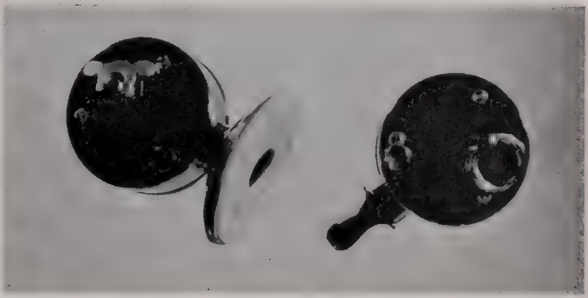

Fig. 6 — The better hearing ear must be "masked" with loud sound in order to accurately evaluate the hearing of a grossly poorer ear — the Barany masker.

to more precise and sophisticated analysis. The quantitation of speech threshold and accuracy for speech itself requires equipment and personnel beyond the range of a general medical examination.

Barany Noise Maker

A gross difference in the hearing of the two ears in a given patient demands one additional test precaution. Significant hearing capacity can be falsely attributed to a severely deafened ear because the patient is unknowingly using the better hearing ear during testing. The skull will carry sound to the better ear with only modest transmission loss. A totally deaf ear will thus be considered to have useful hearing. The general medical evaluator can avoid this pitfall by "masking" out the better ear. The simplest reliable method is by an inexpensive noise-making device applied closely to the good ear — the so called "Barany noise maker" (Figure 6). With the good ear totally preoccupied the examiner can test with words delivered to the handicapped ear in whispered, soft, or loud voice at a distance from arm's length to near contact.

Loss of Cochlear Function

One of the common hearing tragedies of childhood is a unilateral loss of cochlear function as a result of mumps. Unless the opposite ear is "masked out" during testing, a mistaken "modest loss" will be diagnosed and proper concessions for compensatory favorable classroom seating will not be provided. Even worse, purposeless treatment or surgery may be recommended.

In the adult sudden severe or total unilateral loss of hearing with or without tinnitus is a sufficiently common problem to merit general medical awareness and respect. The otoscopic examination will show no abnormality, but voice testing with the better hearing ear masked will demonstrate a gross hearing loss. Temporizing with pointless antibiotic or similar management can dissipate the short-lived reclamation opportunity. Unless aggressive treatment with vascular bed correction (intravenous procaine, heparin, cervical sympathetic block, etc.) is applied vigorously and early, the cochlear deterioration rapidly progresses to irreversibility. Here the general physician contributes tremendously through early recognition of the patient with "sudden deafness."

Meniere's Disease

Meniere's disease is a very common cause of serious sensorineural hypacusis.* It may involve both ears. It originates in the cochlea and for a long time or always it may be a purely cochlear disturbance (Figure 7-a). It causes a sense of fullness in the ear, tinnitus and hearing loss, and is often ignorantly misconceived to be an ordinary auditory tubal closure. The tuning fork, however, will lateralize away from the faulty ear and will be heard better through the canal than when applied to the mastoid process of the affected

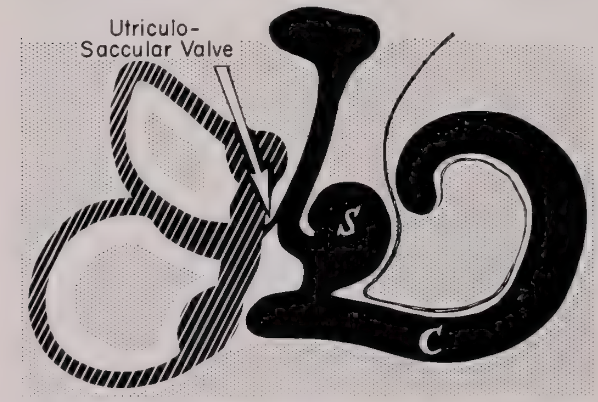

Fig. 7 — (a) Meniere's disease originates in the cochlear segment of the labyrinth and may be confined there with resulting aural pressure, tinnitus, and hearing loss but without vestibular involvement, or

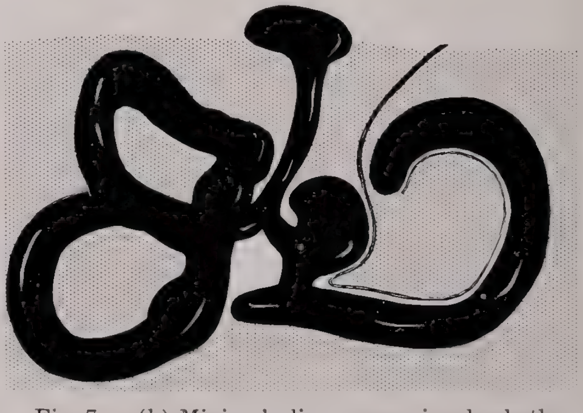

Fig. 7 — (b) Miniere's disease may involve both cochlear and vestibular segments of the labyrinth and result in the better known triad of tinnitus, hearing impairment and episodic vertigo.

---

*See Test Your Word Score Page 607.

ear. When episodic vestibular disturbance occurs to round out the symptomatic picture, diagnosis is relatively easy (Figure 7-b).

Meniere's disease is a "stress" disorder. Management with combinations of neural blocking agents such as diphenhydramine and hyoscine, or with intravenous procaine, heparin, or sympathetic block can be effective in controlling the acute catastrophe. Restoration of normal tonus to the endolymphatic system is, however, difficult, and the hearing tends to remain impaired. Much study is being given to the problem. Certainly prophylaxis is dependent on a "stress-free" life. Here the general physician can be the key to good management.

Tinnitus

The patient whose primary complaint is of tinnitus deserves a respectful hearing. Vibratory sound synchronous with the pulse is often indicative of eddying flow in an intra- or extracranial artery. It may be the first sign of a progressive occlusion and, as such, be exceedingly meaningful. Tinnitus arising from the sensorineural elements of the cochlea can be an early sign of systemic, circulatory or metabolic fault. The cochlear neuroepithelium is distressingly sensitive to toxemias of wide diversity. Tinnitus in the absence of obvious visible aural fault demands an exhaustive systemic assessment.

Other Sensorineural Loss

Progressive sensorineural hearing loss is inherent in certain families and becomes evident in the fifth and sixth decades. However, this incidence is far outnumbered by more specific and controllable etiologic sources such as occupational sound injury, systemic disease, and faulty living habits (stress, tobacco, etc.). Here again the general physician has an important function in retarding the progressive deterioration by assuring optimum general well being and giving sympathetic guidance.

All in all there is ample reward for the physician who recognizes the presence and gravity of hearing loss and gives it the dignity of a place in the medical conscience.

President's Letter continued from page 559.

Administration qualified by position to speak with authority and respond with definitive answers.

At a time when the implementation of the Medicare Law is so imminent, this part of the program should be a stimulus for attendance by every Minnesota physician, for by then the regulations under which we will practice should be codified, available for discussion, and subject to criticism, where indicated, by us, the physicians upon whom the program will depend.

Set aside the time now; attend, participate, and inform yourself fully in this departure from the past and this change which confronts us in the future.

R P Buckley M.D.

R. P. Buckley, M.D.
President
Minnesota State Medical Association

Prejudice

Prejudice is a great time-saver. It enables one to form opinions without bothering to get the facts. — Kitchener (Canada) Record

One trouble with birth control is that it can't be made retroactive.

— Herbert Prochnow

Aortoiliac Occlusion*

PATIENTS WITH occlusion of the terminal aorta and iliac arteries are being seen more frequently, perhaps because of increased familiarity with the Leriche syndrome† and recognition that effective treatment for the symptoms is often available. The average ages in the series reported in the literature have ranged from 49 to 55 years, though many authors[1,2,3] have verified that aortoiliac occlusion can occur in men in their thirties. The symptoms are especially disabling in this still vigorous, still working age group and can force an early retirement.

Clinical Data

A series of 40 private patients, 34 males and six females, has been seen by the surgeons at The Duluth Clinic since 1958.

History

Their ages ranged from 36 to 71 years, with symptoms present for as long as ten or twelve years prior to being admitted to the Clinic. Seventeen had previous evidence of generalized cardiovascular disease (Table 1). The serum cholesterol was abnormally high in 16; 37 were known smokers, 15 of whom smoked two or more packs of cigarettes a day.

Symptoms

The median duration of symptoms was one year. Claudication‡ of the calf was almost as common as claudication of the hip and thigh; six patients had noted claudication only in the lower leg. Eight patients had marked ischemia of the legs, although dependent rubor of the feet as well as other skin changes were infrequent. Both femoral pulses were markedly diminished or absent in 32 patients; in eight the femoral pulse was missing in one leg (Table 2).

Diagnostic Studies

Ninety per cent of the patients underwent translumbar aortography, and distal arteriograms were obtained following the single aortic injection. Direct femoral arteriograms were secured in 17 patients, four of whom had bilateral studies. These x-rays showed partial obstruction of the aorta in two patients and complete occlusion in 11. Seven of the aortograms demonstrated that obstruction of the aorta began just below renal artery level. There was complete obstruction of the right iliac artery in 10 patients and partial obstruction in 11. The left common iliac artery was completely occluded in 22 patients and partially occluded in five. Twelve patients had unilateral and three bilateral obstruction of the superficial femoral or popliteal artery, but in all the patients the profunda femoris artery was patent and furnished adequate runoff circulation.

Management and Results

The Nonsurgical Group

Ten patients did not undergo surgery (Table 3); the symptoms were minor in two; two plan to return in the next several

---

Duluth, Minnesota

months for their surgery; two refused surgery; two underwent exploration, but nothing could be done for technical reasons (one had a horseshoe kidney and the other retroperitoneal fibrosis); and in two the occlusive process was deemed too extensive to be helped.

Sympathectomy Group

In none of the patients did sympathectomy relieve claudication, but it did relieve rest pain in three of the four patients with this symptom. Sympathectomy resulted in dry, warm, and often pinker feet in these patients. It was performed in combination with

endarterectomy in 17 cases and with insertion of a graft in 10 cases.

Endarterectomy

Endarterectomy restored the circulation in ten legs, but four showed evidence of reocclusion of the iliac artery within three years after surgery. In three of the patients who underwent endarterectomy the vessels have remained patent for over five years.

Bypass Graft

Insertion of a bypass prosthetic graft proved to be the most successful technique for relieving aortoiliac occlusion (Figures 1 & 2). Femoral pulses were restored in 16 of 17 legs operated and pedal pulses were restored in 15 of these limbs. The claudication was relieved by the graft in all but one patient; this patient expired following amputation of the limb. Two of the patients who underwent a unilateral grafting operation later redeveloped distal arterial insufficiency, and in one patient this necessitated amputation.

Of the patients who underwent surgery four died, an operative mortality of 13 per cent. Three of these deaths followed unsuccessful endarterectomy or grafting procedures.

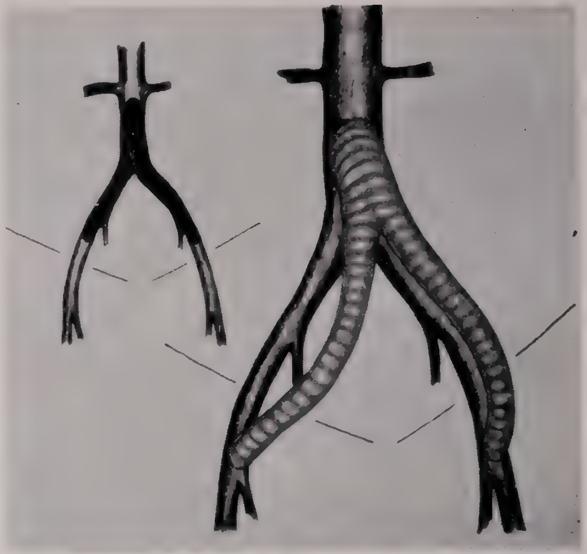

Fig. 1 — Diagram of an extensive aortoiliac occlusion managed by local endarterectomy of the aorta and end-to-side dacron aortofemoral bypass graft.

Report of a Case

A 66-year-old former machinist had complained of increasingly severe intermittent claudication of both buttocks and thighs for two years prior to being seen at The Duluth Clinic. He had noted numbness in the right thigh on prolonged standing or when sitting with his legs crossed. In recent months there had been severe cramping in the thighs and calves after walking one-half block. The cramping disappeared within five minutes if he stood still. His general health had otherwise been excellent and a review of systems elicited no further complaints. He

		Amputated 8 months later	1 leg
Bilateral with bypass	6	Pulses restored	12 legs
		Claudication relieved	12 legs

had smoked two packs of cigarettes a day for many years.

Examination

Examination revealed a healthy, mildly obese male. The blood pressure was 134/82 and the pulse 84 per minute and regular. The heart was of normal size to percussion. There was a grade II/VI coarse systolic murmur in the aortic region which radiated to the neck. The lungs were clear to auscultation and percussion. Abdominal examination was normal. The aortic pulse could not be felt and no bruit was heard.

The feet were slightly pale, and on elevation marked pallor developed. After the legs were lowered the color return was delayed in both feet. Neither the femoral pulses nor the more distal pulses in the legs could be felt.

Laboratory Studies

The hemoglobin was 15.6 grams per cent and the urinalysis was normal. A serum cholesterol was 238 mg. per cent. The electrocardiogram and chest x-ray were normal. Translumbar aortography showed the abdominal aorta to be completely occluded distal to the origins of the renal arteries which were well delineated. Vague shadows outlined the distal external iliac arteries.

Operative Findings

On July 7, 1965, the patient was taken to surgery and the common femoral arteries were exposed by an incision in each thigh. Direct bilateral femoral arteriograms confirmed that the superficial and deep femoral arteries were patent on each side. The popliteal arteries and their branches were also open. At laparotomy the abdominal aorta distal to the renal arteries was found to be nonpulsatile and firm. A small aneurysm was present in the aorta. Pulsations could not be felt in the fibrotic common and external iliac arteries.

Operative Procedure

Bilateral lumbar sympathectomy was performed. Then the abdominal aorta was transected 1.5 cm. distal to the origin of the renal arteries, and after proximal thromboendarterectomy a good brisk flow of blood was secured from the proximal aorta. During this time the renal arteries were occluded with clamps for four minutes. The aneurysm was excised and the terminal aorta oversewn with 3-0 polyethylene suture. A knit dacron bifurcation graft was then anastomosed end-to-end to the proximal aorta. The limbs of the graft were tunneled beneath each inguinal ligament and anastomosed end-to-side to the common femoral artery of each leg. The procedure is illustrated in Figure 3. After completing the right anastomosis, the right leg was profused with blood during suturing of the left limb of the graft. At the end of the operation there was an excellent flow of blood through the graft with good pulses in the common, superficial and deep femoral arteries. Dorsalis pedis pulses could be felt in both feet. Intravenous infusion of five per cent Mannitol solution was begun just prior to the thromboendarterectomy and was continued throughout the procedure. The patient received one unit of dextran and two units of blood during operation.

Postoperative Course

Mild gross hematuria was noted for the first 24 hours after surgery. At no time was there evidence of decreased renal function. Serial determinations of serum urea nitrogen and creatinine during the postoperative course disclosed normal values. The incisions healed by primary intent, and on the day of discharge from the hospital (July 21) there were strong (grade IV) pulses palpable in each foot. The patient has taken mile-long walks without discomfort.

Follow-up Data

Half of the patients have been followed for at least two and a half years and some

for over six years (Table 4). There have been 11 late deaths, the great majority of these due to cardiovascular disease. One third of those patients observed for one year or longer have shown progression of the arteriosclerosis with further diminished peripheral circulation. However, 11 patients followed for three to six years have not demonstrated evidence of further vascular occlusion.

Discussion

Friedman[3] has found an increased incidence of hypercholesterolemia in these patients, and this was likewise present in our series. Hypertension was also frequent in the present study. The smoking history of the patients studied would appear to be heavier than in the general population. Hammond,[4] in a study of 31,733 Minnesota males, ages 40 to 89, found that 26.5 per cent had never smoked and 47.5 per cent smoked one to 19 cigarettes a day or had discontinued smoking. Only 26.0 per cent smoked one pack or more of cigarettes a day.

In Szilagi's[5] experience there was evidence of systemic arteriosclerotic disease in one third of the patients with aortoiliac occlusion. It has been stated that 20 per cent of patients can expect a major cardiovascular complication within five years.[1] Nondiabetic patients have a better prognosis.[6] Most studies have shown 15 per cent late deaths; but the mortality has been approximately 50 per cent in patients followed for five to ten years.[7] The results of this study would appear to be in agreement with these figures.

A fairly certain diagnosis of obstruction of the aorta or iliac vessels can be made on clinical symptoms and findings. Translumbar aortography confirms the clinical impression and outlines the extent of the disease. In patients with femoral-popliteal occlusion aortography has on occasion shown a surprising degree of involvement of the iliac arteries as well. If the patient is hypertensive the dye can be injected at a higher level to obtain renal arteriograms. Although some surgeons have abandoned aortography we continue to believe it an aid that allows us to better plan the surgical approach and to proceed with confidence.

The operative mortality for patients undergoing sympathectomy is low. The mortality has also remained low for either endarterectomy or grafting procedures if good arterial flow can be successfully reestablished. Since an open deep femoral artery will insure continued patency, direct arterial surgery is now offered to almost 90 per cent of these patients. In reviewing the cases and x-rays we felt that in four patients in whom reocclusion of the vessels occurred following endarterectomy and in eight patients who underwent sympathectomy alone bypass grafts could have been successfully inserted. On the other hand, correction of coexistent femoral-popliteal obstruction is best deferred until later.[5,6,8,9] In most cases it will not be required, since lower leg ischemia will have been adequately relieved by aortoiliac reconstruction.

Endarterectomy has been used for patients who have a short segmental obstruc-

TABLE 4

Carcinoma of tongue	1	Condition stable (11 pts. for 3 to 6 years)	16 pts.
Progressive retroperitoneal fibrosis	1		
Unknown cause	1		

tion of the aorta or common iliac artery. Often, however, there is narrowing and fibrosis of the external iliac arteries. Long thromboendarterectomy of the iliofemoral arteries is advocated by Cockett and Maurice,[8] but this type of lesion has not proven easily amenable to endarterectomy in our experience, or in that of others.[1,5,6]

For most patients we feel that the procedure of choice is a bypass bifurcation graft as first suggested by Kunlin[10] and soon thereafter advocated by Linton and DeBakey.[6] The advantages of the graft are its greater ease of insertion as compared to an extensive endarterectomy, the failure of atheroma to develop in the graft itself,[11] and the facility with which the graft can be brought distally to the common femoral artery. Recent results with bifurcation aortofemoral bypass grafts have been gratifying, and we intend to use this method in a higher proportion of cases in the future.

Summary

In forty patients presented the incidence of cigarette smoking was considerably higher than in the general population. Endarterectomy has restored the circulation in a fair proportion of cases, but insertion of a bypass prosthetic graft has been more successful.

ALDRICH SYNDROME*

This syndrome was first described by Wiskott in 1937, and Aldrich, Steinberg, and Campbell in 1954. Approximately 60 cases have been reported, usually occurring as a sex-linked recessive inheritance pattern and characterized by chronic eczema, thrombocytopenia and recurrent infections. The majority of children affected have died as a result of overwhelming bacterial infection. Giant-cell pneumonia, cytomegalo-virus infection and eczema herpeticum have been described as additional complications. Recently a new dimension has become apparent, with reticuloendothelial malignancy developing during the course of the disease. Clinically, the onset is within the first six months of life with the majority of children dying within five years. Treatment consists of supportive care. Immunologically these children have been shown to have a lack of natural-occurring isoagglutinins, lymphopenia, and inability to manifest delayed hypersensitivity.

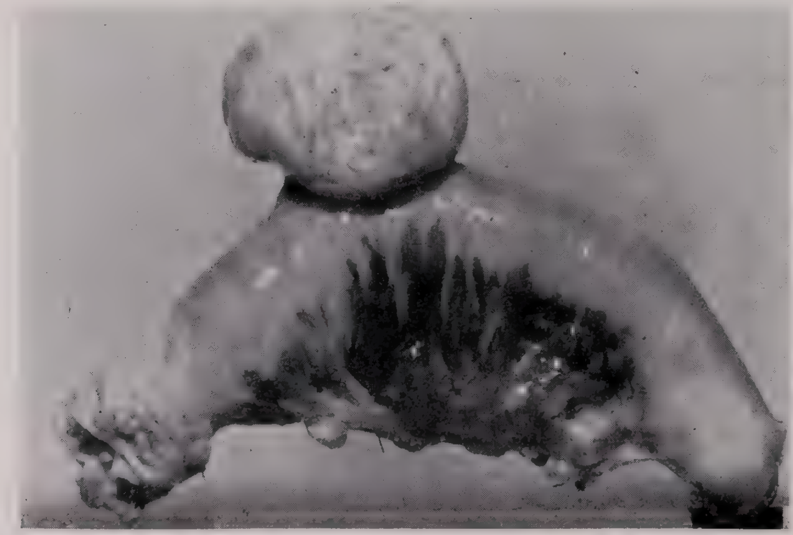
A fat paunch never breeds fine thoughts. — Saint Jerome (345-420 A.D.)

Primary Small

OVER THE PAST 20 years considerable attention has been paid to the problem of tumors of the small bowel. Despite the rarity of these tumors, radiologists and clinicians should be acquainted with the clinical and radiological aspects of this problem, as frequent, unexplained anemias are due to these lesions. Sorlin in 1824 was the first to report a case of small bowel tumor. Good compiled data on 659 tumors of the small intestine, about half of which were benign and half malignant. Sawyer, in 267 cases of complete intestinal obstruction, found that 6.5% were due to small bowel neoplasms. From 1920 to 1960 a total of 650 cases of primary, malignant lesions of the small intestine were reported. According to Good, myomas, adenomas and lipomas are the most common of the benign lesions. Single polyps and hemangiomas are next in frequency. Much less common are aberrant, pancreatic rests, and some systemic diseases which may have tumoral involvement of the small intestine, such as Peutz-Jeagher* and VonRecklinghausen's disease. The most common malignant lesions are carcinoid, adenocarcinoma, lymphoma, leiomyoma and leiomyosarcoma. The correct preoperative clinical diagnosis of a small bowel tumor is rarely made; about 58 of all benign and malignant small bowel tumors are incidentally discovered at operation or necropsy.

Symptoms

Anemia of unexplained origin, partial or complete intestinal obstruction, loss of weight, gastrointestinal bleeding and pal-



Leiomyoma of ileum.

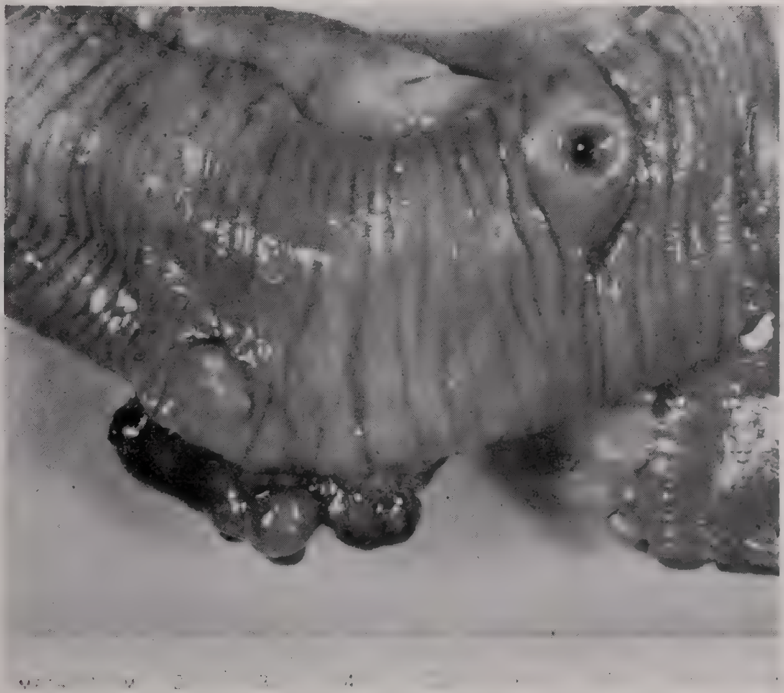
Bowel Tumors

H. G. SCOTT, M.D., F.A.C.S.
Minneapolis, Minnesota
S. GROSSLING, M.D.
Santiago, Chile

pable abdominal mass are the most common clinical features of small bowel tumors. Less common are diarrhea, weakness, fever and pallor. According to Good, 78% of the patients with symptomatic tumors complained of pain or had signs of partial intestinal obstruction. Sixty-eight per cent of the patients had some loss of weight, more common among patients with symptomatic, malignant tumors (71%) than among those with symptomatic, benign tumors (22%). Southan found that about 50% of the cases had a massive hemorrhage as the initial symptom. This symptom is very common in hemangiomas and adenocarcinomas and also in cases with leiomyomas and leiomyosarcomas, the most severe bleeding occurring with leiomyomas. A mass is palpable in about 20% of benign tumors and in 44% of malignant tumors. Fraser has estimated that approximately 65% of sarcomas and only 29% of carcinomas eventually become palpable. While x-rays of the duodenum and proximal jejunum will give the diagnosis in a high percentage of cases, such diagnosis is seldom possible in the distal segments of the small intestine, where the lesion can sometimes be shown only after a very careful



Leiomyosarcoma of ileum showing umbilication of mucosa, source of bleeding.

fluoroscopic examination. Recently cinefluoroscopy has helped greatly in locating lesions in the jejunum and ileum; however, a negative x-ray examination does not mean that the presence of a neoplasm has been excluded.

The diagnosis of small bowel tumors should be seriously considered in all cases of small bowel obstruction and/or intussusception. Serotonin investigation of the urine should be helpful in some cases. Ulcerations, filling defects and blank spaces are common radiological features in neoplasms of the small bowel.

Observations in this Study

This study is based on 32 cases of primary small bowel tumors seen at two Minneapolis hospitals during the past 10 years. These hospitals operate as private, nonprofit institutions under a joint teaching program and are staffed by a number of general surgeons, all of whom have kindly given permission for the review of their cases, 10 of which were seen by one of the authors. Only clinical material has been considered. All autopsy cases have been excluded (Table 1).

TABLE 1

Leiomyosarcoma	3		2	2	1		1	1	2		2
Total	21	1	9	7	8	8	6	11	14	5	8

diagnosis suspected. It is not possible to make an estimate of the duration of symptoms in this group. Of the malignant tumors we found the average duration of symptoms to be from five years for leiomyosarcomas to two weeks for adenocarcinomas.

Symptoms

Signs of gastrointestinal bleeding were evident in the benign tumors though others were asymptomatic. In one patient with an ectopic pancreatic tumor of the duodenum the lesion was suspected by history of epigastric pain and duodenal filling defect by x-rays.

Of the malignant tumors, anemia and melena were the most commonly observed symptoms. Pain, a palpable mass, weight loss and intestinal obstruction were occasional, though not constant symptoms (Tables 2 and 3).

Comments

Clinicians should be alert to the clinical pattern and the radiologist should be aware of the roentgen abnormalities which may be produced by these tumors. In our series the diagnosis was made by the radiologist on the basis of a filling defect of ulceration in 11 cases (34%) (Table 4). In addition to these 11 cases the x-rays gave the diagnosis of small bowel obstruction in seven cases. In this way 18 of our cases were directly or indirectly diagnosed by x-ray, a fact which points up how useful a careful radiological study may be in this type of lesion.

TABLE 4

Tumors Diagnosed By X-Rays

Benign	Duodenum	Jejunum	Ileum
Pancreatic ectopic rests	1		
Leiomyoma	1	1	
Total	2	1	
Malignant			
Lymphoma		2	
Adenocarcinoma	3		
Leiomyosarcoma	1	2	
Total	4	4	

In our series the most common small bowel tumor was the carcinoid, asymptomatic in 65% of the cases; whereas 47% of the adenocarcinomas were symptomatic. The carcinoid may be associated with multivalvular involvement of the heart, and if it is a functioning tumor the urinary determination of five hydroxyindol-acetic acid has been found to be the best test for its diagnosis.

Wide resection of the segment of bowel

TABLE 3

Results of 21 Primary Malignant Small Bowel Tumors at Swedish - St. Barnabas Hospitals (1954-1964)

Type	Surviving	Died	Cause of Death

Haemangioma of jejunum.

involved with its mesentery is the accepted treatment for all malignant lesions. For lymphosarcomas the resection should be followed by roentgen therapy. The prognosis of malignant tumors of the small intestine is relatively poor. None of the patients with adenocarcinoma, who had metastases at operation, survived more than 12 months.

Conclusions

1. Of the 21 malignant tumors, eight were carcinoid or argentaffinomas, six lymphosarcomas, four carcinomas, and three leiomyosarcomas.
2. Of the benign tumors the most common were the leiomyoma and the hemangioma.
3. The most common clinical features were gastrointestinal bleeding, obstruction, abdominal pain and a palpable mass.
4. X-rays provided the diagnosis in 11 patients or 34%. X-ray examination is of paramount importance in the diagnosis of primary small bowel tumors.
5. The surgical excision of malignant lesions is the treatment of choice.
6. The long-term results are excellent in benign tumors but poor in malignant lesions.

Lupus Erythematosus

Presenting as An Acute Abdomen

MORTON H. DUBNOW, M.D.*
JAMES R. MC PHERSON, M.D.**
E. J. WALTER BOWIE, B.M., B.Ch.**
Rochester, Minnesota

ALTHOUGH ABDOMINAL pain is a frequent symptom in patients suffering from systemic lupus erythematosus, it is usually overshadowed by other more significant features of the disease.[1-3] The occurrence of acute abdominal pain simulating a surgical emergency is relatively rare and usually presents a difficult diagnostic problem in a patient known to have systemic lupus erythematosus. It is even more uncommon to find acute abdominal pain requiring surgical exploration as the presenting manifestation. The purpose of this paper is to report such a case and the evidence that ultimately led to the diagnosis.

Report of Case

A 20-year-old white man was brought to the hospital emergency room because of severe abdominal pain. He had been in good health until four weeks prior to admission, at which time he had noted generalized malaise, fatigue, and the passage of black stools. Anemia had been noted by his physician, and parenteral as well as oral iron therapy had been started. Twenty-four hours prior to admission, the patient had noted anorexia and nausea, followed shortly by increasingly severe cramps with mid-abdominal and right lower quadrant pain. No fever, emesis, or dysuria had been noted.

The physical examination revealed a well-developed, well-nourished man in moderate distress from abdominal pain. The pulse rate was 72 per minute, the temperature, 98.0° F., and the blood pressure, 118/68 mm. of mercury. There was generalized abdominal guarding, right lower quadrant tenderness, rebound tenderness, and a positive iliopsoas sign. The bowel sounds were decreased. Rectal examination revealed marked tenderness on the right side.

The hemoglobin concentration was 9.2 gm. per 100 ml. of blood and the leukocyte count was 3200 cells per cubic mm. with a differential count of 15 per cent lymphocytes, 9 per cent monocytes, 75 per cent neutrophils, and 1 per cent eosinophils. The urinalysis revealed grade 2 proteinuria, grade 1 granular casts, grade 1 microhematuria, and grade 1 pyuria.† The thoracic roentgenogram was normal.

Surgical exploration was advised because of the severity of the symptoms and the signs of peritoneal irritation. Of the several possible diagnoses, Meckel's diverticulitis was most strongly suspected. On opening the peritoneum, the surgeon noted an edematous, inflamed omentum. Three feet proximal to the ileocecal valve, an 18-inch length of ileum was thickened, edematous. and reddened. The mesenteric lymph nodes were enlarged and hyperplastic. The spleen was slightly enlarged but otherwise appeared to be normal; also the cecum, terminal ileum, and appendix were normal. Approximately two feet of the ileum with its mesentery was resected and an appendectomy performed; the surgical specimen is shown in the figure. Microscopic examination revealed an inflammatory infiltrate of the muscularis and edema involving the mucosa of the middle half of the resected specimen. This was interpreted as an early stage of regional enteritis. There was no evidence of arteritis.

---

*Resident in Medicine, Mayo Graduate School of Medicine, (University of Minnesota), Rochester.

**Section of Medicine, Mayo Clinic and Mayo Foundation.

†Graded on the basis of 1 to 4.

An adjacent lymph node showed only chronic inflammatory changes.

The patient received 500 ml. of whole blood at operation and 1000 ml. later. The blood was difficult to cross match, which suggested the possibility of a protein abnormality. Electrophoresis of the serum proteins gave the following distribution: albumin, 2.32 gm.; alpha$_1$-globulin, 0.48 gm.; alpha$_2$-globulin, 1.01 gm.; beta-globulin, 0.65 gm.; and gamma-globulin, 2.14 gm. per 100 ml. of serum. The possibility of lupus erythematosus was entertained, but the patient refused further investigation and was dismissed on the eleventh postoperative day.

He was next seen six and a half weeks later, at which time he stressed that he felt perfectly well; however, on further questioning, he admitted to some arthralgia in the wrists and knees and occasional epistaxis. The physical examination was entirely normal. The hemoglobin concentration was still low (9.5 gm. per 100 ml.), and the leukocyte count was 3200 with 35.5 per cent lymphocytes, 5.0 per cent monocytes, 55.5 per cent neutrophils, and 4.0 per cent eosinophils. The erythrocyte sedimentation rate was 122 mm. in one hour (Westergren). The reticulocyte value was 1.8 per cent and the platelet count 108,000 per cubic mm. The peripheral blood smear showed moderate anisocytosis and marked rouleau formation. Urinalysis revealed grade 3 proteinuria, erythrocyte casts, waxy, hyaline and granular casts, and leukocyte casts, as well as microhematuria and pyuria. Electrophoresis of the serum proteins gave a distribution similar to that obtained earlier. The blood urea concentration was 50 mg. per 100 ml. The Venereal Disease Research Laboratory and Kahn tests were weakly reactive, and examination for cryoglobulins was positive. The lupus erythematosus clot test was negative on two occasions. It was noted at this time that there was difficulty getting the specimens to clot, and an active circulating anticoagulant of the type usually associated with systemic lupus erythematosus was demonstrated. Examination of the bone marrow showed it to be hypercellular with prominent capillaries with swollen endothelial cells and thickened walls.

Despite the negative lupus erythematosus clot test, it was thought that the patient had a collagen disease like systemic lupus erythematosus.

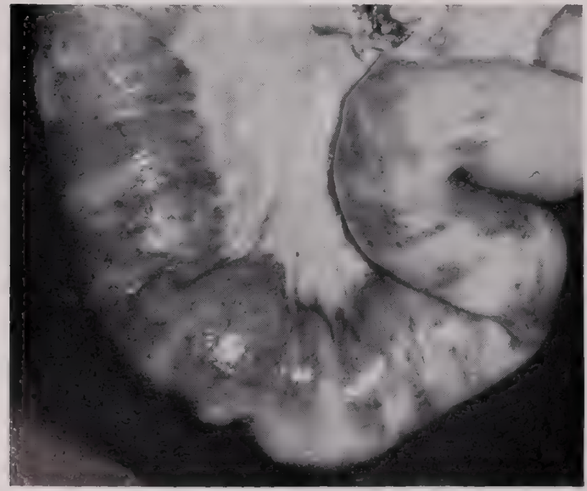

Figure. — Surgical specimen consisting of approximately 2 feet of ileum with its mesentery.

Comment

Severe abdominal symptoms simulating an acute surgical condition are rare in systemic lupus erythematosus. Pollak and co-workers in 1958[4] reviewed 14 such cases and in only two of them was the diagnosis of systemic lupus erythematosus not obvious prior to the onset of abdominal symptoms. Four of the patients presented the clinical picture of acute pancreatitis, with confirmatory laboratory results for this diagnosis in two of the patients. Necropsy studies showed evidence of involvement of the arteries around the pancreas but no actual pancreatic necrosis. The remaining 10 patients presented primarily with nausea, vomiting, fever, and tachycardia. The abdominal pain was dull and occupied either the entire abdomen or the lower half. Abdominal distention was present in nine of the 10 cases, abdominal tenderness was present in every case, and rebound tenderness was striking in seven of the cases. Surgical exploration in these seven cases revealed hemorrhagic edema of the small bowel wall as well as serosanguineous peritoneal fluid. Half of the patients were anemic prior to operation; more than half had leukopenia; and the majority had abnormal urinary sediment.

The diagnostic possibilities in any young patient with acute abdominal pain and anemia include hemorrhagic Meckel's diverticulitis, a hemolytic process, regional enteritis, and the collagen diseases. Inflammation of Meckel's diverticulum causing hemorrhage and peridiverticulitis is rare and is usually associated with leukocytosis. The leukocyte count is similarly increased in hemolytic states with the exception of paroxysmal nocturnal hemoglobinuria. Regional enteritis presenting as an acute abdominal situation is usually accompanied by systemic symptoms and either a normal or an increased leukocyte count. Polyarteritis nodosa should be considered, although here again there is usually leukocytosis. When the combination of leukopenia, anemia, and an abnormal urinary sediment is found in a young patient with abdominal pain, it should suggest the diagnosis of systemic lupus erythematosus. A circulating anticoagulant[5] is found in a number of cases of systemic lupus erythematosus and is most suggestive of this diagnosis. Some of these patients have a negative lupus erythematosus clot test. As the lupus erythematosus phenomenon is intimately related to coagulation, the inhibition of coagulation by a circulating anticoagulant may make this phenomenon difficult to demonstrate. It has been our experience, as in this case, that there has not usually been an associated hemorrhagic tendency; in fact some patients have had a paradoxical thrombosing tendency.[6]

Summary

A case is presented of a 20-year-old man with acute abdominal pain, anemia, leukopenia, and abnormal urinary constituents. A localized area of nonspecific ileitis was found at operation. The presence of a circulating anticoagulant, abnormal serum proteins, and cryoglobulins in addition to positive serologic reactions for syphilis supported the diagnosis of a collagen disease such as systemic lupus erythematosus, despite two negative lupus erythematosus clot tests. It is emphasized that, when leukopenia and anemia are found in association with an acute abdominal condition, lupus erythematosus is a most likely cause even in the absence of associated signs and symptoms of systemic disease.

LERICHE'S SYNDROME*

This syndrome is characterized by chronic atheromatous or thrombotic occlusion of the abdominal aorta above the bifurcation of the iliac vessels. It is associated with pallor of the feet, cold extremities, cramps in the calves, claudication of the buttocks, hips, thighs, and legs, inability to maintain an erection, and finally impotence.

The condition usually occurs insidiously, though it may develop suddenly from thrombo-embolism. If occlusion is marked or complete, surgical resection of the vessels and appropriate transplant is the procedure of choice.

The Penalty of Overweight

Obesity has a definite and deleterious effect upon the liver, and the most significant relationship seems to be the duration rather than the degree of obesity. — Cyril M. MacBryde, M.D., Signs & Symptoms Lippincott Co.

All candidates have two hats in their wardrobes; one to toss into the ring and another to talk through. — North Adams Herald

Salmonella Pullorum Septicemia

SALMONELLA PULLORUM is found very frequently in chickens and has a wide zoological distribution. Human infection is surprisingly rare, with only a few cases of its isolation reported.[1,2,3,4,5,6,7] No human fatalities have been previously reported.

The purpose of this paper is to present the case history, pathological and epidemiological studies of a child who died as a result of *S. pullorum* septicemia complicating granulomatous disease of childhood.‡ The source of the infection was apparently raw eggs.

Case Report

A two-and-one-half-year-old Caucasian male was born at the University of Minnesota Hospitals of a full-term pregnancy and normal delivery. The mother's pregnancy was complicated by fever in the third month of gestation, and her Mantoux test converted strongly positive. She was begun on isoniazid and pyridoxine therapy and continued throughout her pregnancy. Her chest x-rays have always been negative and she has remained in good health.

The patient was considered well until two months of age when he developed fever, lethargy, and a severe diaper rash. At this time, his liver was enlarged 4 cm. below the right costal margin and generalized adenopathy was present. A large hard mass developed in the right cervical area, and a biopsy was taken and interpreted as chronic and acute inflammation. The cultures of the biopsy specimen yielded penicillin-sensitive *Streptococcus faecalis.*

At eight months of age he was gaining weight and developing normally. He then developed a generalized maculopapular rash and a 100.4 degree fever. Laboratory studies at this time revealed a hemoglobin of 9.5 gm.%, and sedimentation rate of 76 mm. per hour. Skin tests including fungal and tuberculin antigens were negative. Skin scrapings from the intertriginous areas showed budding yeast forms typical of monilia and he was placed on oral and topical mycostatin. Oral ferrous sulfate was administered and his hemoglobin rose to 12 gm.% after two weeks.

Progress Report

During the next fifteen months a persistent seborrheic dermatitis of the scalp was present. His spleen remained 2 cm. below the left costal margin and the liver 3 cm. below the right costal margin. At two years of age he developed a temperature of 100.6 degrees rectally and again was admitted for evaluation of enlarged cervical lymph nodes. Skin tests with atypical mycobacterial and triple fungal antigens were all negative. A repeat lymph node biopsy was performed of a right posterior auricular node, cultures of which were negative for bacteria, fungi and acid-fast bacilli. Histologic interpretation was hyperplasia secondary to chronic cutaneous infection and no granulomata were detected. Laboratory studies revealed a 7.2 gm.% hemoglobin, 9,000 white count with 25% neutrophils, 65% lymphocytes, 5% eosinophils and 2% plasma cells. A bone marrow examination was consistent with an iron deficiency anemia. Cultures of the nose, throat and bone marrow were negative for bacterial, fungal, and acid-fast organisms. He was discharged

on oral ferrous sulfate, to which he responded.

Two months later he was admitted for a severe eczematoid rash of the face. A skin biopsy was interpreted as hyperkeratosis with papillomatosis of the epidermis and perivascular round cell infiltrate. A liver needle biopsy was histologically normal. Liver function studies revealed a serum glutamic oxaloacetic transaminase of 32 pyruvate units, serum glutamic pyruvic transaminase of 34 pyruvate units and 0% bromsulphalein retention. Serum electrophoresis revealed total proteins of 7.3 gm.% with 4 gm.% albumin and 3.3 gm.% globulin (0.4 gm.% Alpha 1, 0.7 gm.% Alpha 2, 0.95 gm.% Beta and 1.4 gm.% Gamma). An inflammatory cycle, leukocyte migration test and surface phagocytosis of pneumococci were normal.

Terminal Illness

Following his discharge from the hospital the mother began the feeding of raw eggs in an attempt to "build him up physically." At two and one-half years of age he became acutely ill with a temperature of 103.2 degrees. His spleen was down 8 cm. below the left costal margin; the liver was down 6 cm. below the right costal margin. Laboratory work showed a hemoglobin of 10.0 mg.%; white count was 4,550 with 46% neutrophils, 52% lymphocytes and 2% monocytes. High fever persisted and three blood cultures were drawn. One day later the blood culture reports revealed gram-negative rods, and on this basis intravenous chloramphenicol (150 mg./Kg./day) and penicillin (600,000 units q.i.d.) were administered. Twenty-four hours later his temperature dropped from 103 degrees to 92.5 degrees. Bloody emesis occurred, and a prothrombin time was 50.3 seconds (control 11.3 seconds.) His hemoglobin continued to drop and he died in shock the same day. No other drugs were given during this time and no further laboratory tests were performed. While he was in shock, his liver was rapidly enlarging and quite tender. His death was felt to be the result of both septicemia and acute blood loss.

Blood Culture Studies

The three blood cultures yielded *Salmonella pullorum* in both the broth and pour plates which were sensitive to chloramphenicol and tetracycline. Four stool cultures were negative for salmonellae. Agglutinin titers were 1:80 and 1:60 for *Salmonella typhi* and *Salmonella paratyphi B* respectively. Agglutination tests on the mother and the one-year-old male sibling were negative; however, the father showed no titer for *S. paratyphi B* and positive 1:160 for *S. typhi*. Stool cultures of the mother, father and sibling yielded no *Salmonella*.

Pathology

At autopsy he was a normally developed and well-nourished child. The liver weighed 740 gm. (normal for age — 400 gm.), and there was yellow mottling throughout the parenchyma. The spleen weighed 222 gm. (normal for age — 35 gm.), and on cut section the parenchyma was black, red and hard with a glassy shine. The lungs were wet and engorged throughout. The tracheobronchial lymph nodes were enlarged and firm.

The esophagus possessed a brownish, shaggy mucosal surface. There were numerous ulcerations of the stomach, epiglottis, and vocal cords.

Microscopically there was extensive diffuse necrosis and focal necrosis of the liver, spleen, lymph nodes, bone marrow and Peyer's patches. In association with the areas of focal necrosis, there was moderate monocytic infiltration without leukocytic infiltration. The liver contained nonspecific granulomas, characterized by caseous centers surrounded by a rim of dense fibrous connective tissue containing lymphocytes and plasma cells. One of the tracheobronchial lymph nodes also revealed several small, hyalinized, and fibrotic granulomas which contained several giant cells. The lungs had areas of necrosis, occasional granulomas with giant cells and a chronic confluent pneumonitis. A few pigmented, lipid histiocytes were present in the lungs.

Acid-fast stains and fungal stains revealed no organisms other than hyphael forms of *Candida albicans* in the lungs.

Post-mortem bacteriologic studies detected *S. pullorum* in the splenic tissue and blood. *C. albicans* were isolated from the mouth, skin, adrenals, lung and spleen. There were no other fungal or acid-fast organisms recovered. Viral isolation using human amnion, monkey kidney and Hela cells yielded no virus in the stool, liver, spleen or lung.

Epidemiological Investigation

The mother reported that shortly after this child's birth, she had heard from a physician that the infant's feedings could be "fortified" with raw eggs. She stated further that when the child did not eat well, he was often given egg yolk in his milk. The patient's maternal grandfather owned a feed mill in South St. Paul and he obtained eggs for the families from one of his feed customers (Farm L). The patient's family (four members) consumed about four dozen eggs a week. The patient and his sibling were reported to receive on occasion four raw egg yolks a day. The use of this supplement was accelerated in the five months preceding the patient's death.

An investigation was made of Farm L in October, 1963, where 300 hens were in production. The hens originated from two hatcheries that had had negative pullorum check tests for two years. The birds were housed in the lower level of an old but sound barn and were kept in at night and yarded in the daytime when weather permitted.

The pullets were fed a commercial chick starter ration which contained two animal origin products, meat and bone scrap, and fish meal in proportions that are a trade secret. The producing birds were fed a commercial egg-laying mash. The only animal origin ingredients in this ration were meat and bone scrap and preserved animal fat. Neither of these feeds was medicated with antibiotics.

On November 1, 1963, the farmer permitted testing of 22 of the older hens. The stained-antigen, rapid, whole blood test (plate agglutination test) was used.[8] Ten of the hen bloods were agglutinin-positive (45.5%). Five of these reactor hens were purchased for bacterial isolation. *S. pullorum* was isolated from the ovaries of all five hens. The identification of this serotype was confirmed in the Enteric Laboratory, Communicable Disease Center, U.S. Public Health Service, Atlanta, Georgia, according to the methods of Ewing and Edwards.[9]

The eggs produced on this farm were used by the immediate family and close relatives and sold to drive-in customers only. The wife of Farmer L stated repeatedly that no family members or relatives had been ill, and therefore she was sure that their eggs were not the source of the patient's infection. Due to her hostility no one else was cultured for the presence of salmonellae, and a customer list could not be obtained. No *S. pullorum* isolates have been made in the Division of Laboratories, Minnesota Department of Health, since the death of this patient; therefore, no further cases have been traced to this source. No eggs were cultured and no environmental specimens were taken from the barnyard.

Case Discussion

This two-and-one-half-year-old male had numerous infections during his life, which terminated as the result of *S. pullorum* septicemia. The underlying cause of his recurrent infections, hepatosplenomegaly, cervical adenopathy and eczematoid rash was not determined but his clinical and laboratory findings were most consistent with the syndrome described by Berendes, Bridges, and Good.[10,11] A recent review of this subject by Carson et al.[12] summarizes the findings of this form of granulomatosis. This case probably represents a sporadic form of the disease, as there is no other family member known to be affected. It is of interest that in the paper by Carson et al. four of thirteen cases had *Salmonella* isolates out of which one was septicemic with *S. typhimurium*.[12]

Histiocytosis X, Aldrich's Syndrome,* sarcoidosis and dysgammaglobulinemia were also considered but not documented. The illness of the mother during pregnancy was suggestive of tuberculosis or fungal disease, but repeated attempts to isolate these organisms were unsuccessful. No cases of granulomatous disease in the offspring of mothers receiving either isoniazid or pyridoxine have been reported.

The question may be raised as to whether this child's entire disease process could have been the result of chronic *S. pullorum* infection. This hypothesis seems untenable since many cultures of different sites were taken throughout his course and *S. pullorum* was not encountered until his final episode. The history of increased consumption of raw eggs in the five months preceding death implies that a larger number of *S. pullorum* organisms were available as an infecting dose; also no granulomas have been reported with any type of *Salmonella* infection.

The granulomas found at autopsy in lymph nodes, liver and lung are those described by Berendes et al.[10,11] and by Carson et al.[12] (Figure 1). Giant cells were encountered in the lungs and were apparently related to fungal infection.

Superimposed upon the pathology of the granulomatous disease is that of the salmonellosis. The focal necrosis and monocytic infiltration of the liver, spleen, lymph nodes, Peyer's patches and bone marrow are characteristic of *Salmonella* septicemic infection. The monocytic infiltration with the lack of leukocytic response was striking in the areas of focal necrosis and has been described in typhoid fever.[13] The enlarged liver with yellow mottling and the glossy red-black parenchyma of the spleen are also classically seen in fatal cases of *Salmonella*.[13,14]

This case is primarily important as it relates to the problem of human infection with *S. pullorum*. The possible deleterious effects of the feeding of raw eggs, under-cooked eggs or dried egg powders to humans who are more susceptible to infection either by age or underlying disease processes warrant some further review of this problem.

Most isolations of *Salmonella pullorum* are made from chickens and turkeys. It has also been isolated from other birds, occasionally from animals, and rarely from man. The organism is carried in the ovaries of the hen, its natural host, asymptomatically. Some of the eggs laid by the hens will be infected and chicks hatched from the infected eggs will become carriers.[15]

Investigations of the occurrence of salmonellae in market eggs indicate their presence is rare.[16,17,18] *S. pullorum* has been found in eggs marketed in the United States, but in small numbers.[19,20,21] Dried egg

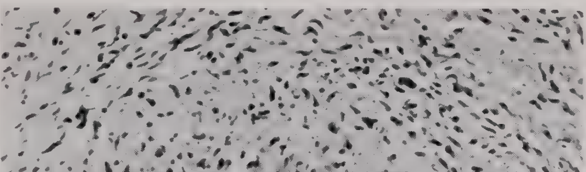

Fig. 1 — Photomicrograph of granuloma of the liver showing caseous center surrounded by a zone of fibrous tissue with deep staining nuclei and plasma cells. [x40]

---

*See page 571.

powder, on the other hand, was found by Soloway et al.[22] to contain 11% *S. pullorum* isolates in 5,198 samples of dried egg.

Salmonella pullorum and *gallinarum* are known to have a high degree of specificity for an avian species, especially chickens.[20,21] They have been considered by some to be nonpathogenic for man.[25,26] However, there are reported isolations of these serotypes from man. Seventy-one reported instances of human *S. pullorum* infection have been reported in this country.[1-7] Three reports have dealt with outbreaks of gastroenteritis.[2,6,7] The source of the infections was apparently raw eggs in foodstuffs and eggnog. The remainder of the cultures have been found in sporadic cases of diarrheal disease and one culture has been isolated from a healthy carrier.[1]

Neither septicemia nor death from *S. pullorum* has been previously reported. Saphra,[27] in studying 7,779 cases of salmonellosis between 1939-1955, of which 318 were fatal, reported no cases of *S. pullorum* infection.

Salmonellae are most often isolated from children under the age of five.[26,28] Children in this age group are apparently more susceptible to infection, although this may be allied to increased parental concern which leads them to seek medical attention and subsequent diagnosis.

What the relationship is between the dosage of *Salmonella* organisms and disease is not definitely known. Recent studies have shown that a much greater dose of *S. pullorum* is needed to cause disease in man than several other serotypes tested.[30,31,32] In normal adult prison volunteers previously immunized against typhoid, the disease-producing dose of *S. pullorum* ranged from 1.28×10^9 to 16.0×10^9 organisms,[24] whereas the dose of five other *Salmonella* serotypes were in the range from 1.25×10^5 to 4.45×10^7.[28,29]

What dose our patient was receiving is not known. The number of organisms could have been very low or absent at times. On other occasions, it is conceivable that the dose may have been high; if the entire contents of a bottle were not consumed, it remained at room temperature for a time, and then was added to and/or warmed again prior to consumption. There was no medical history of typhoid immunization and the medical history indicates that this child possessed an impaired resistance to infection because of the underlying pathophysiological condition in addition to his young age.

The chickens may have been infected from three possible sources: the hatchery, the farm environment, or the feed, as all are known to be the origin of avian salmonellosis. As the chickens came from a "clean" hatchery, this seems an unlikely source. While numerous salmonellae have been recovered from animal feeds or ingredients, *S. pullorum* was not isolated from 3,459 samples examined in three recent investigations.[33,34,35]

Summary and Conclusions

A case report of *Salmonella pullorum* septicemia as a terminal event is presented, apparently acquired from the consumption of raw eggs. The clinical course and pathological findings demonstrate an underlying granulomatous disease similar to that described by Berendes, Bridges, and Good.[10,11]

The pathology related to the salmonellosis was diffuse focal necrosis and monocytic infiltration of the liver, spleen, lymph nodes, Peyer's patches and bone marrow. The presence of granulomas in the liver, lung and lymph nodes is related to the patient's underlying granulomatous disease process, and determination of their etiology was unsuccessful.

The epidemiological study showed this child was receiving eggs from a flock heavily infected with *S. pullorum*. This points out the need to take great care in the feeding of raw eggs, under-cooked eggs or dried egg products to humans known to be more susceptible to infection, until such time as these are known to be free of salmonellae. It also emphasizes the need to further control zoonotic disease* in its animal and avian reservoirs.

IT'S THE LAW

Testimony of Consultant Specialist Need Not Be Corroborated by Referring Physician

Under the rule that a physician consulted for treatment, rather than for examination only, may testify as to a patient's subjective symptoms and his conclusions based on those symptoms, the Wisconsin Supreme Court held that a specialist was a doctor consulted for purposes of "treatment," even though the specialist did not prescribe any treatments to the patient directly.

The patient, injured in an automobile accident, brought suit for personal injuries. After the accident, he had consulted his physician for difficulties with his back and neck. When the patient continued to experience such difficulties, despite treatment by his physician, the physician referred him to a specialist in orthopedics for diagnosis. The specialist examined him, took X-rays, and made a report to the physician. A few months later, the physician sent the patient to the specialist again. Treatment was prescribed directly by the physician, who saw the patient frequently.

At the trial, the specialist testified as to his opinion concerning the patient's injuries, based on his examination and X-rays, and also on the medical history and subjective complaints which the patient communicated to him. The patient's own physician did not testify. The trial court concluded that the specialist's testimony was legally insufficient unless corroborated by the physician. Objection to the specialist's testimony had been made on the ground that, since he was an examining doctor, not a treating doctor, he could not testify on subjective matters.

In overruling the trial court's conclusion, the State Supreme Court said that there was no evidence that the patient had consulted the specialist for the purpose of obtaining testimony for the trial. However, even if this had been one purpose of the consultation, it would not have barred the specialist's testimony, since the consultation had been made for "bona fide purpose of treatment." Obtaining a specialist's diagnosis to aid a physician in treatment is a "bona fide purpose of treatment," the court concluded.

Felkl v. Classified Risk Insurance Corp., 129 N.W.2d 222 (Wis., June 30, 1964)

*Papyrus Ebers**

Constipation and Diarrhea

A glance at the Papyrus Ebers dispels once for all any idea that Constipation is a scourge of the modern world brought about by modern conditions of living and eating. For page after page from the very beginning of the papyrus the Scribe sets down purgative after purgative . . . Castor Oil figures in not a few of them; unfortunately for the patients, in only one prescription is it the sole ingredient:

Berries-of-the-Castor-oil-tree
Chew and swallow down with Beer in order to clear out all that is in the body.

But they are not all as simple as that; nor as effective, one may venture to add.

Leaves-of-the-Castor-oil-plant	1/4
Dates-of-the-Male-Palm	5/6
Cyperus-grass	1/16
Stalk-of-the-Poppy-plant	1/16
Coriander	1/16
Cold Beer	1/2

Keep moist, strain, and take for four days.

Another remedy for Constipation which not only claims to act as a purgative but drives out all the diseases in the body, smacks more of a dawn-of-history cocktail than a purgative. It consists of Half-an-Onion mixed in Froth-of-Beer, and is further described as 'A Delightful Remedy Against Death.' The remedy still persists in the shape of the 'life-saver' dispensed at the public bar, but the ingredients are no longer the same and its purgative action has long since disappeared.

The remedies for Constipation are appropriately followed by a succession of remedies 'to stop the diarrhoea.' As the following examples show their employment was purely empirical:

Green Onions	1/8
Freshly-cooked-Gruel	1/8
Oil and Honey	1/4
Wax	1/16
Water	1/3 dena.

Cook and take for four days.

Figs	1/8
Grapes	1/8
Bread-dough	1/32
pit-corn	1/32
Fresh Lead-earth	1/64
Onions	1/32
Elderberry	1/8

SING: O, Hetu!
Again: O, Hetu!

Which in the circumstances appears to be a very appropriate word to chant.*

Minimal Hypertension and Insurance Mortality

A Plea for Early Treatment

EARL T. OPSTAD, M.D.*
Minneapolis, Minnesota

THERE ARE indications which point to the desirability of treating the early minimal hypertensive patient in order to prevent avoidable excess mortality. In a study of 3,900,000 entrants[1] contributed by twenty-six life insurance companies from 1935 to 1953, the increased mortality of minimal hypertension is clearly demonstrated. It is well to bear in mind that these blood-pressure recordings were made during the normal working day and that these subjects represent a large group of people who can be considered to be apparently normal, healthy individuals living normal lives.

Age vs. Mortality

Most physicians would not treat as a hypertensive a 35-year-old man with a blood pressure of 144/90; yet the expected mortality over a ten-year period of 1,000 standard risks at this age would be 20. In the Build and Blood Pressure Study of 1959,[1] it was revealed that males in this group with no other impairment had a mortality ratio of actual to expected deaths of 199%. With this mortality of 199%, 40 men would die during this same ten-year period.

Forty-five-year-old males with a blood pressure of 156/95 were found to have a mortality ratio of 336% — an excess mortality of 108 lives out of a thousand in a ten-year period. The increased death rate is due principally to cerebrovascular accidents and diseases of the heart including coronary heart disease.

The Borderline Hypertensive

Objections are made to the possible variables that can occur during the life insurance examination. The Medical Letter[2] states that the examining doctor under-reads the blood pressure often enough so that "it would be a serious error not to consider the possibility that this practice is sufficiently widespread to have a marked effect on the outcome of the study." On the other hand, a frequently heard objection is raised by William Evans[3]: "A slightly raised blood pressure met with in applicants for life-assurance benefits . . . is inseparable from the natural anxiety and excitement peculiar to this special examination." Therefore, it is of more than passing interest to note the incidence of arteriosclerotic heart disease experience in a four-year follow-up of the Framingham Study[4] of borderline hypertensive patients without heart disease. The rate was found to be 62 per thousand as compared with 26 per thousand in normotensives. Borderline hypertension was defined as that between 140/90 and 160/95. If men with high relative weight and high cholesterol were omitted, the rate for subjects with borderline hypertension

---

*Associate Medical Director, Northwestern National Life Insurance.

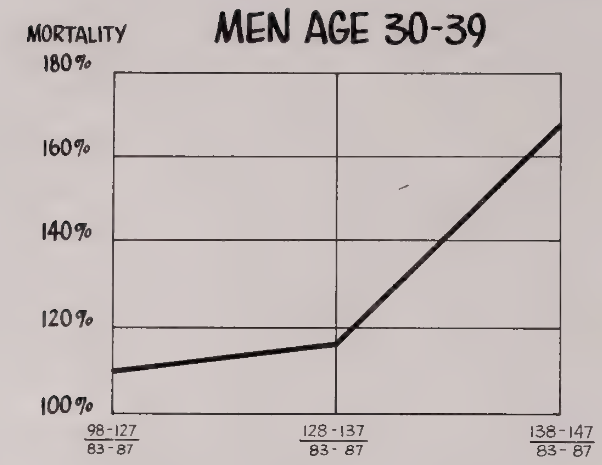

Figure 1

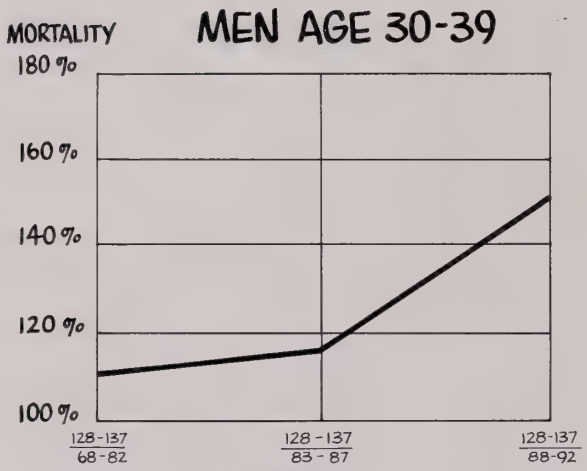

Figure 2

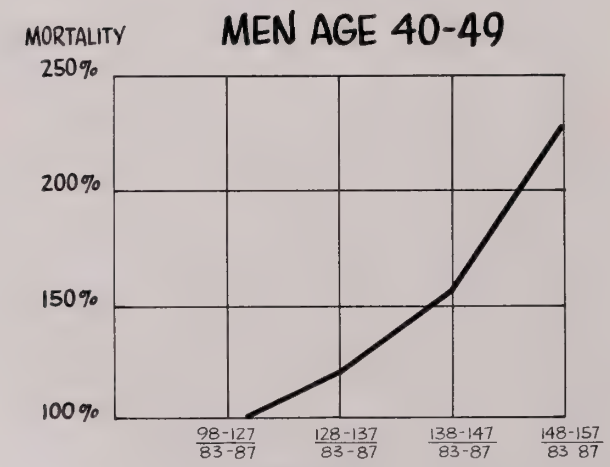

Figure 3

would be 37/1000 as compared with 17/1000 for normotensive persons.

Treatment of the Hypertensive

As important as it is to treat severe hypertension, it is even more important to treat the early minimal hypertensive patient in an effort to stave off the increased mortality that can be statistically demonstrated in minimal hypertension. Several studies[5-9] reveal frequent reversibility of cardiac failure, cardiomegaly, abnormal electrocardiograms, and retinopathy, with only moderate success in the treatment of severe hypertension. Moyer, Heiden, Pevey and Ford[5] stated that although there was no difference in renal function in treated patients in the group with mild to moderate blood-pressure elevation between the control period and the follow-up period of twenty-eight months, the similar, untreated group showed a reduction in renal blood flow from 966 cc./minute to 755 cc./minute. In the group with severe hypertension there was no change in renal function before and following treatment; however, the comparable untreated group showed a marked reduction in function in only twenty-four months. Significant improvement in electrocardiograms and decrease in heart size were noted in both treated groups. Van Dyne[6] reported improvement in renal function, retinopathy, heart size, and electrocardiographic changes in twenty treated cases. Newman and Robertson,[10] in a report on 22 cases, feel that there is little doubt that adequate control of the blood pressure is a major factor in preventing the recurrence of cardiac failure in patients with hypertension. Kirkendall and Armstrong[11] were able to demonstrate a "very active repair process" in the form of widespread collateral circulation to effectively bypass the obstructed arterioles of the retina in treated hypertensives. If these changes can be reversed, it should be reasonable to assume that they can also be prevented.

Reversibility of Hypertension

Hypertension hastens the process of arteriosclerosis. The rate of change is undoubtedly dependent upon many factors, such as the severity and the duration of hypertension and the individual response to it. It has been contended, however, that keeping the blood pressure normal or reduced will not prevent hypertensive complications.[12] Housel, Kelly, and Daly,[13] on the other hand, state that earlier treatment of hypertension by the family physician is virtually preventing hypertensive encephalopathy and malignant hypertension from being seen, whereas twenty years ago several cases could be observed on the wards of any large hospital on any day. Smirk[14] feels that grade four retinal hypertensive changes rarely occur in a patient whose blood pressure is properly treated. Studies demonstrate not only the reversibility of abnormalities but also a definite decrease in mortality with effective treatment and control. Moyer et al.[5] reported a mortality of 25% in a treated group with an average survival time of 22 months. Their untreated group had a mortality of 75% with an average survival period of 11 months. Their study of 31 patients with malignant hypertension revealed only two of 13 treated patients dead, with an average survival time of 30 months as contrasted to the untreated group in whom the mortality was 17 out of 18 patients, with an average survival period of 14 months.

Treatment vs. No Treatment

Leishman,[15] in a study of 400 cases, reported far fewer deaths among patients whose hypertension was treated either by surgery or with drugs, the mortality rate being roughly one third of that observed in the untreated cases. The incidence of cerebral hemorrhage was markedly reduced.

Aurell and Hood,[16] in an analysis of postmortem and case records, found that the mortality from cerebrovascular lesions was decreased in patients with controlled hypertension and that no patient was under continuous good regulation of blood pressure at the time of the stroke.

In a study of 2,775 patients treated medically or surgically before and after 1950, Kinsey, Sise, and Whitelaw[17] showed a statistically significant decrease in the five-year mortality rates in the medically treated cases.

In a 10-year follow-up, White[18] reported the effectiveness of surgical treatment as compared with no treatment. Perry and Schroeder,[19] in a four-year study, showed a significant lower mortality rate among the 209 medically treated cases.

The Cause of Death in Hypertension

The effects of hypertension were graphically illustrated by Clawson[20] in a review of 2,597 fatal cases. Death was ascribed to myocardial insufficiency in 43%, to coronary artery disease in 36%, to cerebral hemorrhage in 14%, and to renal insufficiency in 7%. Obviously, it is almost impossible to demonstrate at what level of hypertension these changes begin to occur; however, there is strong indication that hypertension is already well established at levels of 140/90, with this figure being statistically more significant in the younger age groups. Mortality increases slightly from the lower levels of blood pressure up to 140/90; but at this point the curve rises sharply (Figures 1 and 2).

Labile hypertension is also often considered unimportant. In a study of 2,510 policyholders who were considered substandard risks solely because of mild elevated blood pressure, Pollack, McGurl, and Plucinski[21] found that the differences in mortality between the nonlabile group and the labile group were not statistically significant.

The Systolic vs. Diastolic Pressure

There is a common belief that if the

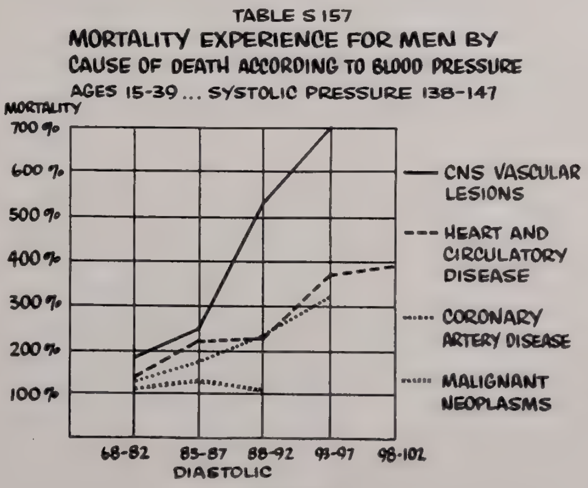

Figure 4

systolic pressure rises, it is not harmful as long as the diastolic level remains normal. That this is incorrect is well illustrated in Figure 3 which clearly depicts the rapidly rising mortality with increasing systolic pressures in the presence of a normal diastolic pressure.

Much is said about a "basal" blood pressure which is obtained after a period of recumbency. If this reading is normal, then the patient is not classified as hypertensive. How valid is this criterion? Does it reflect the true physiological process? Is it the condition that prevails during problem and stress situations, e. g., in driving and in other daily competitive situations? Are we in a position to say that it is of no consequence if the blood pressure is increased during the waking hours as long as it is normal while at rest or sleep? Life insurance statistics based on blood pressure readings obtained during the working day indicate that this is not so. In males under 40 with blood pressure in the range of 138/88 to 147/92, fatal heart disease is more than twice and cerebral vascular accidents more than five times as frequent (Figure 4).

Conclusions

Any objection raised in regard to the manner and means of blood pressures obtained from life insurance examinations cannot explain the orderly, constant, and definite increase in mortality seen with every small increment of increased blood pressure starting with levels that are considered low.

Reassurance in the treatment of early hypertension was acceptable when there was little else to offer; but this does nothing to increase the hypertensive patient's longevity. With the safe, effective antihypertensive drugs available today, the physician can no longer ignore slight elevations of blood pressure any more than he can ignore the early signs of any other disease process. The significantly increased mortality in early hypertension clearly defines the physician's responsibility.

STARLING'S LAW*

If the inflow, and consequently the outflow, of blood from the heart is kept stable, the work that the heart has to do is greatly altered by a change in the peripheral resistance. As a result of incomplete emptying the residual blood can increase the diastolic volume, with consequent rise in the venous pressure. Due to an associated lower arterial pressure, there would be a poorer coronary blood supply, and the heart would become fatigued, and bradycardia could result.

Total Right Hepatolobectomy

for A Metastatic Neuroblastoma

PAUL M. BROWN, M.D., F.A.C.S.
JOSEPH T. HART, M.D.
Portland, Oregon

For most of a decade partial hepatectomy has been performed for benign and malignant primary tumors and cystic lesions of the liver. In the past few years metastic tumors in the liver have also been excised when the site of origin was believed to be under control. Woodington and Waugh in 1963 reported a 20% 5-year survival in 25 such cases, with an operative mortality of 4%. In their series, as in most, the majority of the metastatic tumors have involved the left lobe of the liver.[19]

Wangensteen[17] reported the first total right hepatectomy to be successfully performed in this country in 1951. In 1953 Pack and Baker[14] outlined the technique of controlled resection of the right lobe of the liver — a technique now generally accepted.

The majority of hepatic tumors in children are fortunately benign and many are best left undisturbed.

Of eighteen hepatic tumors in children cited by Gross,[6] all of which were surgically explored, only five were resectable; two of the eighteen children survived: one a child with a hamartoma locally excised and the other an infant with multiple hemangiomas which were later treated with radiation therapy.

Mersheimer in 1953[12] and Clatworthy in 1956[3] reported the first successful right hepatolobectomy case reports for malignant tumors in children. Gross attempted right hepatolobectomy for metastatic neuroblastoma but lost the child due to an air embolus.[7] Clatworthy has since been interested in this subject but does not have a case where right hepatolobectomy has been carried out in a child for metastatic disease.[4]

Removal of up to 80% of the liver substance has been successful in experimental animals. Pack and Islami[15] cite regeneration in rats within 12 to 18 days and in dogs within five weeks following resection of large portions of liver. They further discuss a patient reoperated two years after total right hepatic lobectomy, where regeneration produced final liver dimensions greater than the original liver size. They suggest that regeneration might be influenced by cortisone administration and, further, that the inevitable elevation of portal pressure in the remaining left lobe is highly beneficial in promoting rapid regeneration.

Case Report

A four-year-old white male was first admitted to St. Vincent's Hospital on January 19, 1964, because of a large slightly tender mass in the right upper quadrant. He was otherwise asymptomatic. A chest roentgenogram and pelvis films were normal. Intravenous pyelography revealed a normal but displaced right calyceal system; intravenous cholangiography revealed delayed filling and displacement of the gallbladder to the left. A complete blood count, urinalysis, bilirubin, prothrombin time and cephalin flocculation were within normal limits. VMA determination[18] was .76 micrograms per 24 hours.

Initial Procedure

On January 23, exploration of the abdomen through a right rectus retracting incision revealed a metastatic nodular involvement of the entire right lobe of the liver. The left lobe appeared normal. The nodular enlargement of the right lobe was continuous with a huge mass originating in the region of the right adrenal gland. The kidney was entirely separate from this mass and displaced downward. The mass was considered unresectable at that time. A biopsy of a representative portion of the liver edge revealed undifferentiated neuroblastoma.

The patient received a tumor dose of 1025 roentgens over a period of two weeks and was then discharged from the hospital on February 8, 1964. After considerable re-evaluation it was the consensus of opinion that the child should be re-explored with the prospect of resecting the tumor-containing right lobe of the liver.

Definitive Procedure

At the time of readmission on March 9, 1964, the liver mass was approximately 50 per cent smaller than prior to radiation. On March 10, two right inferior vena cavagrams were carried out at the suggestion of Dr. William Clatworthy, Children's Hospital in Columbus, Ohio. Since there was no encroachment or roughening of the vena cava, right hepatic lobectomy under general anesthesia with moderate hypothermia was done on the following day. At this time the patient weighed 16 kilograms (35.25 lbs.).

Findings

At operation the large multinodular mass was found to involve only the right lobe of the liver, with a border of 2 to 3 cm. of normal appearing tissue just to the right of the falciform ligament. The left lobe of the liver was free of any irregularity. One periportal lymph node, examined by frozen section, contained only inflammatory tissue. There were no other periaortic nodes, nor was there any evidence of spread into other areas of the abdomen.

Technique of Operation

The cystic duct and artery were identified and separately ligated and divided. Following this the right hepatic duct and right hepatic artery were isolated, doubly ligated and divided. At this point the liver was lifted slightly and the adrenal gland dissected from its bed. The right adrenal vein was then isolated, and five or six smaller hepatic veins draining into the vena cava were also isolated, ligated and divided without difficulty. The bare area of the liver was next separated from the diaphragm with extreme care as the vena cava was approached. The portal vein was then visualized, making it apparent that there was actual tumor growing into its bifurcation; therefore, the portal vein was transected at a point 2 cm. proximal to its bifurcation, where it was widely patent. An end-to-end anastomosis of the left lobe branch of the portal vein to the main portal vein was made out, using #00000 arterial silk, thus allowing an adequate inflow of the portal vein blood into the remaining left lobe of the liver. The anterior surface of the liver just to the right of the falciform ligament was then incised, giving greater mobility to the specimen and to the remaining two large hepatic veins that were still attached to the vena cava near the diaphragm.

Operative Complications

At the junction of one of the large hepatic veins with the vena cava a laceration developed and an air bubble was noted moving slowly along the inside wall of the translucent vena cava. Constant positive pressure-bag breathing by the anesthesiologist allowed quick recovery of the air bubble, and the rent in the cava was repaired with #00000 arterial silk suture. It was in a difficult location, however, and a considerable amount of time elapsed from the onset of the positive-pressure breathing.

Bradycardia

Just as the laceration was closed, the patient developed a marked bradycardia and an idioventricular rhythm. The pericardium was quickly opened and the heart was found to be quiet, flaccid and empty. Cardiac massage and 1 cc. of 1:1000 adrenalin into the right ventrical reinstituted a normal rhythm.

Completion of Operation

The remainder of the operative dissection was straight forward, the liver transection passing through the left edge of the quadrate and caudate lobes. The common duct was not drained. Gelfoam was applied to the cut edge of the liver as there was insufficient falciform ligament to reperitonealize this raw surface. The wound was then closed in conventional fashion. Two large Penrose drains were led out from the bare area on the under surface of the diaphragm. Two chest tubes, one from the pericardium and one from the right thorax, were led out of the ninth thoracic interspace and attached to Glover suction.

Estimated blood loss was approximately 1850 c.c.; the patient received 1700 c.c. of whole blood during the procedure. On the following day his hematocrit was 40% and hemoglobin 13.8 gm.

The Specimen

The specimen removed weighed 760 gm. and measured 16 x 14 x 8 cm. As noted at operation the intrahepatic portal vein contained gross tumor, but the cut edges along the left border and the posterior surface of the specimen were not involved.

Postoperative Course

Cardiovascular

The patient's EKG pattern was nodal following the cardiac arrest, but towards the end of the operation it reverted to a normal sinus rhythm with good P-waves. As the patient was rewarmed during the first few hours postoperatively, his EEG pattern reverted to normal. Constant venous pressure monitoring for the first three postoperative days was accomplished by an inferior venacava catheter which had been left in place following the cavagram performed the day before. His venous pressure determinations were used as a means of titrating small volume salt-free albumin and blood administration needs at one to two-day intervals. His urine output was measured hourly, and his postoperative hemoglobin determination stayed in the range of 12.5 to 13.5 gm. with an appropriate red blood cell count.

Blood Chemistries

The morning of surgery the patient's chemistries revealed the following in milliequivalents: sodium 138, potassium 5.1, chloride 99, with a total protein of 7.9 gm. per cent. His prothrombin time was 39% although he had not been on anticoagulants. On the second postoperative day his alkali reserve was 24, potassium 4.1, sodium 126; and his chlorides were 78 milliequivalents. These last two were promptly corrected to chlorides and sodium of 94 and 138 milliequivalents respectively by the following day. Two days after operation following a good postoperative day and as the patient was gradually being warmed, he developed a transient seizure. His fasting blood sugar was 40 mg. per cent. He improved markedly with the intravenous administration of 25 c.c. of 50% glucose. On the following morning he became lethargic and quite unresponsive. His fasting blood sugar then was 20 mg. per cent. Immediately after the intravenous administration there was a quick clearing of his lethargy, and he sat up in bed and talked.

Nutritional Intake

For the next several days until his blood sugar levels became stable, he received, in addition to his regular fluid and electrolyte requirements, occasional intravenous injections of 25 c.c. of 50% glucose. By the fourth postoperative day the abdominal wall drainage from his Penrose drain sites had lessened considerably. He was given 12.5 gm. of salt-free albumin on that day and the next. By the fifth postoperative day he was ambulated and his urine output was quite constant at about 700 c.c. each 24 hours. His oral intake of up to 1000 c.c. of fluids allowed reduction of intravenous fluids.

Convalescence

On the sixth postoperative day his temperature rose to 102.4 rectally. His electrolytes were then normal. His Penrose drains had been removed the previous day. He also developed a peculiar tremor of his hands and arms reminiscent of the "liver flap" seen in cirrhotic adults. By the eighth postoperative day he seemed stronger but remained irritable; his tremor became less prominent, coincident with an increased oral protein intake. At this point he developed a pericardial friction rub.

Antibiotic Medication

His temperature continued to spike daily to 102 to 104 degrees, and on the tenth postoperative day he was placed on Achromycin. The following afternoon he developed marked abdominal distention and hyperperistalsis and had a number of loose green bowel movements. The Achromycin was then discontinued. Chloromycetin was started on the thirteenth postoperative day, but the temperature spikes continued. Although the patient seemed otherwise improved, his abdomen remained slightly distended and diffusely tender; but there was no localized area to suggest an abcess. Films showed slight elevation but good motion of the diaphragm. At about this time he was transfused with 250 c.c. whole blood on two separate days. The chloromycetin was discontinued and Unipen* (Sodium Nafcillin) was started on the seventeenth postoperative day with a prompt improvement in his temperature curve toward normal. The child continued to do well and improve in appetite and activity. His abdomen remained moderately distended during this period of time. His friction rub disappeared.

---

*Wyeth Laboratories.

By the thirteenth postoperative day ascites was noted, which gradually subsided without paracentesis. His abdominal girth decreased, antibiotics were stopped, and his early sedimentation rate of 80 mm. dropped to 16 mm. in one hour. His electrolytes and complete blood count were normal, and his prothrombin time was 68% at the time of discharge on April 5, 1964, twenty-five days following right hepatolobectomy. He was subsequently seen in the office and continued to make a satisfactory recovery with further reduction in girth of the abdomen, increase in weight and improvement in strength and color.

Subsequent Fate

Between August 1964 and January 1965 he was placed on chemotherapy using Vincristine sulphate. Pulmonary metastases were noted which regressed for three months, then grew rapidly, leading to death in February 1965.

Discussion

Neuroblastoma, to be cured, must be diagnosed early and treated radically. Those children with visceral metastases generally have a much better prognosis than those with skeletal involvement. Gross[8] reports that 98% of children with bony metastases die. Surgery, irradiation and chemotherapy are the modalities employed jointly for the treatment of neuroblastomata in most children's medical centers. Swenson,[16] however, believes that neuroblastoma should be simply biopsied and then treated by radiation if extension into the renal fossa makes removal hazardous. Chapman and Sheridan[1] found that radiation did not materially increase the 30% 14-month survival figure in their series of 32 patients. The Boston study indicates that 99% of the deaths occur within two years after diagnosis.

Gross and associates[8] advocate radical surgical removal of all available gross tumor, followed by postoperative radiation up to a total dose of 3600 to 4000 r. Complete removal of tumor followed by irradiation in 21 such patients resulted in an 88% two-year survival. Even where palliative excision of the great bulk of the tumor and x-ray were used, 64% of 14 patients survived for two or more years, even though in these instances it had been obvious to the surgeon that some tumor had remained.

The operative technique was greatly facilitated by the adequate exposure provided by the thoracico-abdominal incision and incision of the diaphragm radially towards the vena cava.

Ligation and division of the cystic duct and cystic artery are no problem, but careful isolation of both the right and left main branches of the portal vein is essential.

The separation of the diaphragm from the bare area of the liver affords a clear approach to the junction of the large hepatic veins with the vena cava and, in addition, increases mobility of the specimen. Ligation and division of adrenal veins and six to eight smaller, short hepatic veins that pass from the right lobe into the vena cava must be done with extreme care to avoid hemorrhage and air embolus.

Air embolus is a real entity and can lead to death if unrecognized. If the anesthesiologist quickly increases the positive pressure on his breathing bag, venous return to the right heart is restricted. This is helpful in that the air bubble will drift distally and emerge from the cava at the site of the tear or leak.

Transection of the liver 1 to 2 cm. to the right of the falciform ligament is facilitated by a dusky line of demarkation, evident through Glisson's capsule, representing the effect of ligation of the right hepatic artery.

The bradycardia, idioventricular rhythm* and subsequent cardiac arrest occurred because we failed to heed Starling's Law.**

Protracted breathing allowed recovery of the air bubble and distention of the vena cava facilitating its repair; but, as a result, cardiac and coronary filling were incomplete. Had we punctuated this period of bag breathing even occasionally to allow the lung parenchyma to fill properly, perhaps we could have avoided the cardiac arrest.

---

*See Test Your Word Score Page 607.

**See page 590.

The abnormal prothrombin time suggesting a depletion of glycogen stores was not adequately protected with 5% and 10% glucose intravenously to avoid the profound hypoglycemia we observed.

Conclusions

After biopsy and radiation therapy, regression in the size of the tumor can occur sufficiently to provide an otherwise inoperable lesion of the liver.

Removal of up to 80% of the liver substance has been successful in experimental animals. Pack and Islami[15] cite regeneration in rats within 12 to 18 days and in dogs within eight weeks following resection of large portions of liver. They further discuss a patient reoperated two years after total right hepatic lobectomy, where regeneration produced final liver dimensions greater than the original liver size. They suggest that regeneration might be influenced by cortisone administration and further suggest that the inevitable elevation of portal pressure in the remaining left lobe is highly beneficial in promoting rapid regeneration.

A case of successful right hepatic lobectomy for metastatic neuroblastoma is presented.

BERENDES SYNDROME*

Fatal Granulomatous Disease of Childhood

This syndrome was first described by Berendes, Bridges and Good in 1957 and is characterized by recurrent suppurative lymphadenitis, chronic dermatitis, chronic pulmonary disease and hepatosplenomegaly. The disease is usually familial, occurring in males with the onset of bacterial infections in the first year of life. The course is usually progressive with continuous or recurring infections. Death occurs between four to 13 years of age, usually of extensive lung involvement but has also resulted from hepatic disease or from septicemia. Pathologically there is granulomatous formation present in the lungs and liver with an unusual abundance of plasma cells. No bacterial, fungal or mycobacterial agents have been recovered from these lesions. To date the underlying physiologic defect leading to repeated bacterial infections is unknown. Adrenal steroids when used with antibiotic therapy appear to have a suppressive effect on the progressive course of this disease.

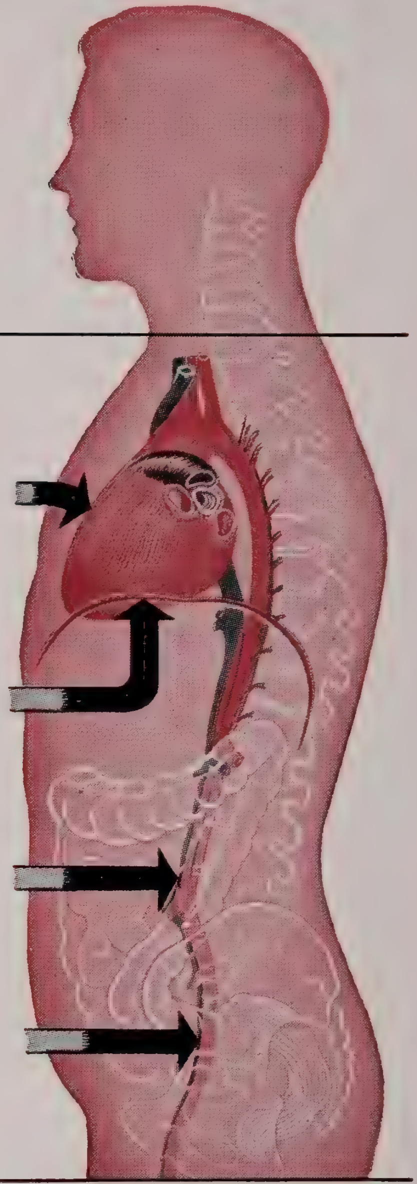
Drive Safely

Most auto accidents occur on Saturday and Sunday. It's a great life if you don't weekend.

In Cardiovascular



Increased intrathoracic and intra-abdominal pressure from straining

METAMUCIL®

brand of psyllium hydrophilic mucilloid

Metamucil Powder: 4, 8 and 16-ounce containers. Instant Mix Metamucil: cartons of 16 and 30 single-dose packets.

Patients–

Metamucil

...to prevent straining at stool and its adverse effect on blood pressure, cardiac output and pulmonary circulation.

Average Adult Dosage:

One rounded teaspoonful of Metamucil (or one packet of Instant Mix Metamucil) in a glass of cool liquid one to three times daily.

SEARLE

Research in the Service of Medicine

Thanks to Dexamyl®

brand of
dextroamphetamine
sulfate and amobarbital

she can say "No thank you" to the crêpe suzette.

'Dexamyl' does more than most anorectics. Because it curbs appetite *and* lifts mood, 'Dexamyl' can encourage the discouraged dieter to stay on her diet.

The mood lift with 'Dexamyl' can make the difference between the success or failure of her diet plan.

Formulas: Each 'Dexamyl' Spansule® Capsule (brand of sustained release capsule) No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid [Warning, may be habit forming]. Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital [Warning, may be habit forming].

Principal cautions and side effects: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Insomnia, excitability and increased motor activity are infrequent and ordinarily mild.

Before prescribing, see SK&F product Prescribing Information.

The Management of Bell's Palsy

BELL'S PALSY can produce a serious and permanent disability. Unfortunately, for years it has been assumed that 80% of patients recover spontaneously. Dr. Jerome Hilger,* in the November issue, has pointed out that, in fact, only 55% of patients have a complete return of function.

In our modern society, which demands much personal contact, great importance is placed on one's physical appearance; thus the psychological, as well as financial, disability of one who must meet the public with a deformed, twisted face can be appreciated.

Although a permanent partial or complete facial paralysis does not threaten the patient's life, the treatment may be compared to that of a patient who has acute appendicitis. In acute appendicitis only a small percentage of patients die of their disease, but because the treatment is so successful and the possible effect of the disease so serious, most, if not all, are subjected to appendectomy.

In recent years the results of surgical decompression have vastly improved, and the side effects of the treatment have been reduced to only the temporary time loss and discomfort of operation. With modern otologic microsurgical techniques, the patient can be expected routinely to experience no further damage to the facial nerve by the surgery, to have no postoperative hearing loss or loss of balance, and, probably most important to the patient, to have no postoperative cavity. Except for the insignificant scar from the incision, the patient's physical appearance is in every way the same as it was before operation.

Initially, a careful neuro-otologic examination is necessary to make the diagnosis of Bell's palsy by exclusion of other lesions. The exact level of involvement can be determined by testing the various branches of the facial nerve. It is useful for the surgeon to know whether the greater superficial petrosal nerve is functioning, as determined by ability of the involved side to produce tears; whether the stapedius nerve is functioning, as detected by determining the presence or absence of the stapedial reflex to loud sound; or whether the chorda tympani nerve is functioning, as tested by either chemicals or an electric taste tester.

A patient with complete Bell's palsy can be treated medically, and the treatment often is effective in producing a cure. The basic problem is to determine which patient should have surgical decompression and when such decompression should be carried out. In this respect, it is important to follow some general guidelines, especially in situations which carry a poor prognosis: (1) Facial-nerve decompression is indicated in all patients who have Bell's palsy accompanied with pain. (2) Decompression is indicated if there is no sign of recovery within three weeks of the onset, regardless of test results. (3) Surgical

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered fo prolonged sitting at desks, pianos, typewriters and drafting boards. The stresses set up by the heavy, forward-tilted head and trunk, balanced precariously on an insufficient base, result in strain of the dorsal musculature, particularly at the low lumbar level.

The unusual muscle-relaxant and analgesic properties of 'Soma' make it especially useful in the treatment of low back sprains and strains. 'Soma' is widely prescribed ☐ **to relieve pain** ☐ **to relax muscles** ☐ **to restore mobility.**

Indications: 'Soma' is useful for management o muscle spasm, pain, and stiffness in a variety o inflammatory, traumatic, and degenerative musculoskeletal conditions. It also may act to normalize motor activity in certain neurologic disturbances.

Contraindications: Allergic or idiosyncratic reactions to carisoprodol.

Precautions: 'Soma', like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g., meprobamate.

Side Effects: The only side effect reported with any frequency is sleepiness, usually on higher than recommended doses. An occasional patient may not tolerate carisoprodol because of an individua reaction, such as a sensation of weakness. Other rarely observed reactions have included dizziness, ataxia, tremor, agitation, irritability, headache, increase in eosinophil count, flushing of face, and gastrointestinal symptoms.

One instance each of pancytopenia and leukopenia, occurring when carisoprodol was administered with other drugs, has been reported, as has an instance of fixed drug eruption with carisoprodo and subsequent cross reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. In cases of allergic or hypersensitivity reactions carisoprodol should be discontinued and appropriate therapy initiated. Suicidal attempts may produce coma and/or mild shock and respiratory depression.

Dosage: Usual adult dose is one 350 mg. tablet three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white tablets and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

intervention is also indicated when nerve excitability is absent or is decreasing with the daily tests. (4) Decompression should be considered for the patient whose appearance has an unusual importance for his livelihood.

Finally, physicians should be aware of the poor spontaneous recovery rate of complete facial paralysis as a result of herpes oticus. Almost all patients with such infection have serious permanent disability. In these patients, the nerve involvement is usually in the petrous portion of the temporal bone. Likewise, basilar skull fracture may involve the petrous portion of the temporal bone. Since the entire facial nerve is surgically accessible, decompression in either of these two uncommon conditions should not be delayed.

Jack L. Pulec, M.D.
Rochester, Minnesota

Patch-Grafting of the Gastrointestinal Tract

CLOSURE OF A large defect in a hollow viscus can be a formidable task. Large perforations resulting from ulceration of the duodenum or distal part of the esophagus are common examples of this problem. Other causes are trauma and resection of invasive malignant lesions. When primary closure cannot be made by suturing the margins of the defect together, other techniques must be used.

In the January issue of MINNESOTA MEDICINE, Thal and associates[1] describe patch-grafting of defects in the gastrointestinal tract with the seromuscular surface of an adjacent loop of bowel. They also used this method of grafting for large defects in the urinary tract. When considering this method of closure for defects in the gastrointestinal tract, one must take note of the authors' warning about grafting in the duodenum and stomach. They have shown experimentally that seromuscular patch-grafting is not applicable to the stomach or first part of the duodenum unless measures are taken to ablate acid production. Otherwise the incidence of perforation of the graft is extremely high.

Full-thickness pedicle graft of intestine offers another method for bridging a large defect in the duodenum. A segment of jejunum, excised from continuity but with mesentery and blood supply intact, can be opened longitudinally on the antimesenteric border and sutured to the margins of the defect. This type of graft might be less susceptible to immediate perforation than a seromuscular graft, but the incidence of subsequent perforation would undoubtedly be high unless measures were taken to reduce gastric acid production.

Relevance of the Spread of Cancer Cells to Chemotherapy

AS EARLY as 1869 tumor cells were demonstrated in the circulating blood. Since then many studies have further established the presence of cancer cells in the peripheral circulation, in blood vessels draining tumor sites, in the bone marrow, in lymphatic tissue, and in various body cavities. Even though the greater percentage of tumor cells released into the blood stream from a large primary tumor fail to survive, this spread of such cells may be responsible for the death of a cancer patient as the invading cells interfere with normal cell functions. The success of excisional surgery for malignancy is limited, therefore, because of the frequency with

which cancer cells are transported to distant sites.

Prevention of cellular spread is difficult, as it most likely takes place continuously once the tumor has invaded blood vessels and lymphatics and penetrated into a serous cavity. Many methods have been accepted by surgeons in attempts to prevent this spread, such as (1) early ligation and division of the veins draining the tumor sites, (2) occlusion of the bowel lumen on each side of the tumor, (3) covering of the tumor-bearing tissue, and (4) limited manipulation of the tumor. Certain drugs, such as nitrogen mustard, when used to wash a wound at the time of surgery, have been found useful for destroying cells. Many drugs given internally have also been found to be ineffective against solid tumors either because these drugs are too toxic for the host to endure or because their anticancer properties are limited.

No positive method of increasing host resistance to malignancy in humans has been demonstrated, despite the many successful experiments in the field of chemical carcinogenesis.

The finding of tumor cells in the blood should not be used as evidence that radical surgery for malignancy is unjustified, as we know that the tumor-cell-destroying capacity of the host is evidenced by the disappearance of large numbers of cells from the blood. Though it is also true that the identification of tumor cells in the peripheral blood of a patient with a malignant disease is associated with a significantly decreased survival, this identification of such cells does not indicate a fatal outcome for all patients. The course of the disease may be changed by curative surgery, by decreased infectivity of the disseminated cells, by chemotherapy, or by host resistance factors. Further work in the field of adjuvant chemotherapy and host resistance is vital for an increase in survival rates of cancer patients.

Aneurysmal Abscess

ALTHOUGH NOT common, infection can involve the walls of arteries to the point of dilatation and aneurysm formation. The aorta, pulmonary arteries, or the peripheral arteries may be involved. Invasion can result from (1) embolization of organisms, (2) entrance of organisms at site of previous disease or degeneration, and (3) direct extension from an adjacent suppurative process. The classic example of the first type is the mycotic aneurysm secondary to subacute bacterial endocarditis. With regard to the second type, there is sufficient precedence to suggest that diseased arteries are susceptible to bacterial invasion, for example, damaged heart valves and patent ductus arteriosus. In recent years the term "cryptogenic" has been applied to a type of mycotic aneurysm caused by deposition of bacterial organisms at the site of atherosclerosis.[1] In these aneurysms, as contrasted with endocarditis cases, results of blood cultures often are negative (the causative organisms are *Salmonella* and *Staphylococcus*) and the effects of intensive antibiotic therapy are disappointing. The ef-

fective treatment of mycotic aneurysm is surgical, with excision of the diseased tissue and graft substitution.

Early symptoms may be nonspecific, with only malaise and fever, but eventually a tender, pulsating mass presents itself. The tendency of mycotic aneurysms to rupture eventually has been stressed by several authors.

True mycotic aneurysm must be differentiated from false aneurysm, which results from complete rupture of all coats of an artery, in which the lumen then communicates with a sac whose wall consists of periarterial structures and clot; and which also results from secondary hemorrhage due to septic erosion of a contiguous artery. Secondary hemorrhage may present as a rapidly enlarging pulsatile mass. Into this latter classification, the infected pulsating hematoma, the cases of Drs. Huebl and Read* more properly belong. As pointed out by the authors in the January issue, the treatment of the dual problems of infection and vessel destruction is difficult, and prevention of the initiating causes must be the first order of defense.

Pulmonary Surgery for Emphysema

It is well known that cysts can occupy most of one side of the thorax without causing apparent disability if the opposite lung is normal. It is imperative to assess patients with air cysts critically by a complete battery of pulmonary function and blood gas-tension studies. It is likewise imperative to understand the operative indications and hazards. There are four types of cysts.

A Single Bulla in an Otherwise Normal Lung

The pulmonary function is normal, and operation could be advised to prevent chronic recurring infections and to prevent compression of normal lung parenchyma.

Multiple Bullae

There usually is well-preserved ventilatory function. Diffusing capacity may be normal or reduced, depending on the status of the remaining lung. A vigorous medical approach should be advised to prevent further destruction of remaining lung tissue.

Bullae as Part of Generalized Emphysema

There is severe ventilatory impairment, a low diffusing capacity and, frequently, abnormal blood gas tensions. Operation usually is contraindicated and is extremely hazardous; a vigorous medical program is indicated.

Cysts and Bullae Related to Cystic Degeneration of the Lung

This is seen in the honeycomb lung in histiocytosis X, scleroderma, and chronic diffuse interstitial fibrosis. Operation is of no benefit because the pathologic process is diffuse.

I think that the term "emphysema" implies chronic irreversible obstructive airway disease and that bullae are part of the generalized pulmonary disease. The best chances for good results depend on early recognition and a vigorous approach to medical treatment.

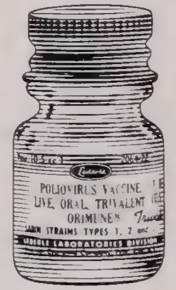
Doctor...two important Lederle products for routine office procedures



single-dose vials for convenient and economical polio immunization

ORIMUNE®

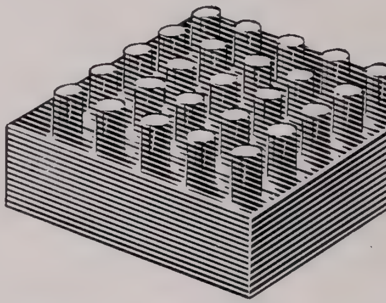
POLIOVIRUS VACCINE, LIVE, ORAL

TRIVALENT

SABIN STRAINS, TYPES 1, 2 and 3

Fast, simple administration—and economy for the patient—make the new 0.5 cc single-dose vial of ORIMUNE Trivalent ideal for private practice. (Packaged 5 to a box with 5 sterilized disposable droppers for your convenience).
(Also available in 2 cc and 2 drop dosage forms).
Only 2 doses required for complete, initial immunization for patients more than a year old.

Effectiveness—may be expected to confer active immunity against all three types of poliovirus infection in at least ninety percent of susceptibles only if given at full dosage, as directed. No characteristic side effects have been reported. There are, however, certain contraindications. These are, broadly: acute illness, conditions which may adversely affect immune response, and advanced debilitated states. In these, vaccination should be postponed until after recovery.
In infants vaccination should not be commenced before the sixth week of life. Do not give to patients with viral disease, or if there is persistent diarrhea or vomiting. ORIMUNE and live virus measles vaccine should be given separately.
Dosage—initial immunization: two doses each given orally at least 8 weeks apart. (Give a third dose to infants at 10-12 months). Booster immunization: one dose, given orally. See package literature for full directions.



simplifies routine screening

TUBERCULIN, TINE TEST

(Rosenthal) Lederle

Swab • Uncap • Press • Discard

Comparable in accuracy and reliability to older standard intradermal tests*, but faster and easier to use. Since TINE TEST is relatively painless it should receive greater patient acceptance. Results are read at 48-72 hours. The self-contained, completely disposable unit requires no refrigeration and is stable for two years.
Side effects are possible but rare: vesiculation, ulceration or necrosis at test site. Contraindications, none; but use with caution in active tuberculosis. Available in boxes of 5 (new individually-capped unit); cartons of 25.

Intracerebral Hemorrhage

Of the many varieties of cerebrovascular disease, intracerebral hemorrhage continues to be, once it is fully developed, a frustrating and difficult disease to manage. The pathologist also finds that analysis of the evolution of the condition to its final picture is difficult because the underlying or associated pathologic changes are often distorted or destroyed by the end result of the pathologic change, the hemorrhage itself.

Epidemiologic studies indicate that the incidence of intracerebral hemorrhage has decreased during the last several decades. This lowered incidence is likely the result of potent antihypertensive treatment, which reduces the degree of hypertension itself as well as minimizes the secondary arteriolar changes. Chason[1] and his associates point out that clinical hypertension was invariably present in patients who died of intracranial hemorrhage. More than three fourths of their patients had, on pathologic examination, hypertensive changes in the vessel. It is hoped that continued use of antihypertensive medication will lead to a further reduction in the incidence of hypertensive intracerebral hemorrhage.

Many other diseases cause, though much less frequently than hypertension, intracerebral hemorrhage. Every physician should remember that small hemorrhages occur and remain within the substance of the brain and that such hemorrhages generally are not fatal. Because the spinal fluid usually is normal initially (slight zanthochromia may be seen in four or five days in some patients), a diagnosis of ischemic infarct may be made.

Letter to the Editor:

Neither I nor any doctor is against essential vital statistics such as the central, hard-core information on the birth certificates. What I am complaining about is the peripheral information which now covers three sides of the birth certificate and which will certainly be extended to cover the fourth side unless a cure can be found: a cure for the disease of regimentation that is beginning to encompass all of us. The flood of paper work is just one of its symptoms. The five minutes it takes to complete these particular blanks are relatively insignificant except that they are the final straw on the back of the camel, the "one more case" that finally turns an endemic problem into an epidemic.

What possible use to anyone except a statistically inclined government worker are the questions pertaining to "date of mother's first marriage," or "years of education," or "illegitimate?" No one who delivers babies asks these questions as a part of the prenatal workup — why should they be necessary in the post-partum period? It is extremely unlikely that this information could add anything to the individual care of any patient; yet it is just this kind of information that is so dear to the statistically inclined people at all levels of state medicine. It is good that some doctors are interested in this phase of medical knowledge, but it should not be my job to do their leg work.

The chairmen of both the Maternal Mortality and the Perinatal Mortality Committees of the State Medical Association have told me that their committees have never made use of these supplements and that they have no plans to use them in the future. Yet the OB-GYN Committee for the State Association gave the official medical blessing to make the supplement possible.

Our time is valuable and in short supply. Let us conserve this precious commodity and parcel it out in areas where it will do the most good. Let us not add to our own burden by taking the time to fill in every blank that crosses our desks, for these blanks are a major manifestation of a serious disease that has already reached epidemic proportions. We can keep it from becoming pandemic only by drawing a line here and now. . . .

The Editor's Soliloquy

The Fallacy of "I Read it in a Book"

People often quote the written word as if it were the gospel truth, defying the spoken word that denies it: "Put it down in black and white" or "I'll have to see it in print before I believe it." Even a self-evident spoken truth often seems to carry less conviction than the faintest ink. Why can't our word be as good as our bond?

"I saw it in the paper," "I read it in a magazine" appear to convey a finality that only a few cynical listeners would presume to challenge.

Our ingenuous belief in the incontestability of the printed phrase is

to help relieve pain in common anorectal disorders

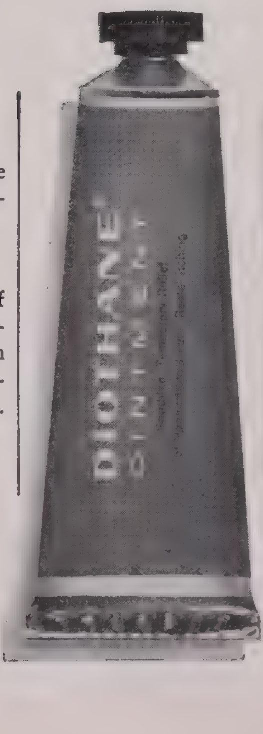
“non-caine” Diothane®

Diothane—with its chemically distinct “non-caine” anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.



CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Merrell

apparently based on the fact that the iterated word is ephemeral and on repetition can be distorted; whereas the printed word, being concrete and permanent, is thereby invested with inviolability.

Perhaps historically and legally there are extenuations for our sublime faith in the printed word. Time was when literacy was confined to a very small minority of any population, and the illiterate masses, being in no position to prove otherwise, humbly assumed that all that these scholars read and wrote was the Truth, categorical and ex-cathedra.

Further credibility accrues to the printed word because a man can be held legally responsible for what he utters in print; for slander or falsehood he can be sued for libel. So we have deluded ourselves into assuming that greater care and calculation have gone into the selection of the printed word than into the impromptu choice of the spoken one.

But alas! we are still too naive! Our news and advertising media capitalize on our penchant for believing what we see in black and white. We easily succumb to slanted news propaganda and to blatant commercial advertising. As all that glitters is not gold, so, much that appears in print is far from being incontrovertibly true.

In this era of biased news and fulsome advertising, who would not credit the oral analysis of an impartial and objective news commentator more than the written lines of a prejudiced or chauvinistic reporter! And who would not give greater credence to the spoken word of a reliable doctor than to the printed blurb on a patent medicine advertisement?

But with the captivating charm of one who appeals to us, or the factual monotony of the other, like the drowsy drone of the greenfinch, how are we to know the difference?

Carl O. Rice, M.D.

Mom says: A perfectionist is a nice thing to have around the laboratory but a horrible thing to have around the house. — C.O.R.

June 1966 Medical License Examination

At the February 11-12, 1966 meeting of this Board a request made by the President of the Senior Medical Class of the University of Minnesota Medical School was given consideration.

It was the determination of the Board that the request could be granted and the regular June, 1966 examination (which would regularly be held June 21, 22 and 23, 1966) was re-scheduled for June 14, 15 and 16, 1966 in order to accommodate graduates who wish to leave for their internships.

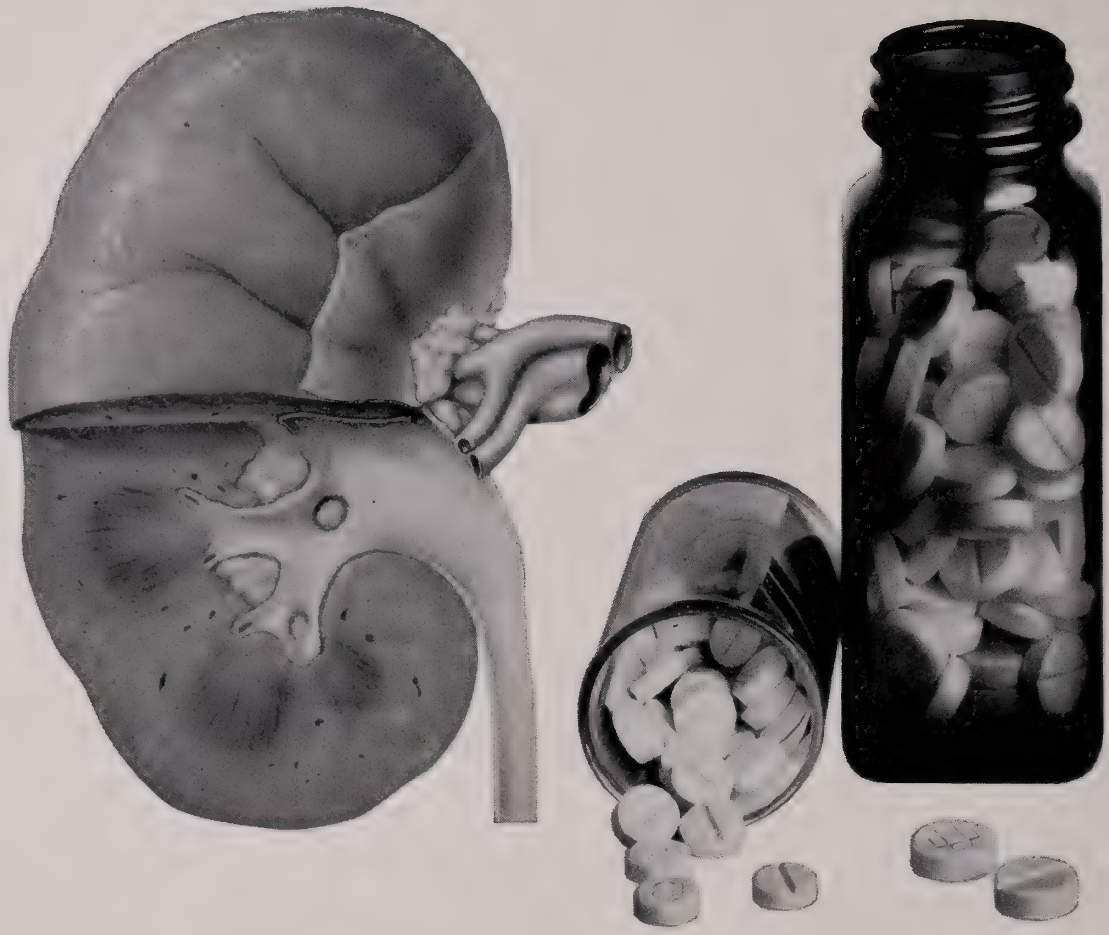
at Merck Sharp & Dohme...



understanding... precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

Curbstone Consultation

Kernicterus*

QUESTION: How often does kernicterus occur in infants?

ANSWER: Kernicterus statistics vary depending on how the bilirubin is measured and how healthy the infants are in all respects other than jaundice. Kernicterus occurs in about 50% of infants with indirect bilirubin of 30 mg%. The disease has been reported at indirect bilirubin levels under 15 mg%, and infants have survived indirect bilirubin levels of over 35 mg% without kernicterus. Kernicterus is not easy to diagnose in its early stages.

The main features of the 1st phase are hypotonia, lethargy and poor suck; of the 2nd phase: spasticity, opisthotonus and fever; of the 3rd phase: diminution or disappearance of spasticity. The 4th phase appears in later infancy — extrapyramidal cerebral palsy.

An excellent article on the diagnosis of the different stages of kernicterus is Praagh's article in Pediatrics 28:870, December 1961. This author points out that 16% of the cases of kernicterus were unsuspected in the neonatal period.

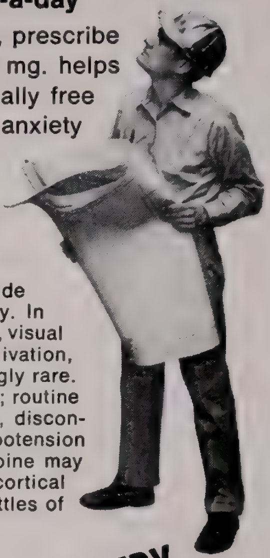
Blueprint for dealing with tension due to stress—Prolixin—once-a-day

For the patient who must be on the job mentally as well as physically, prescribe Prolixin. The prolonged tranquilizing action of as little as one or two mg. helps him cope with tension all day long. Markedly low in toxicity and virtually free from usual sedative effects, Prolixin is effective in controlling both anxiety associated with somatic disorders and anxiety due to environmental or emotional stress. Patient acceptance is good—because Prolixin is low in cost, low in dosage and low in sedative activity. Prescribe Prolixin.



Side Effects, Precautions, Contraindications: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photosensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders. **Available:** 1 mg. tablets. Bottles of 50 and 500. For full information, see Product Brief.

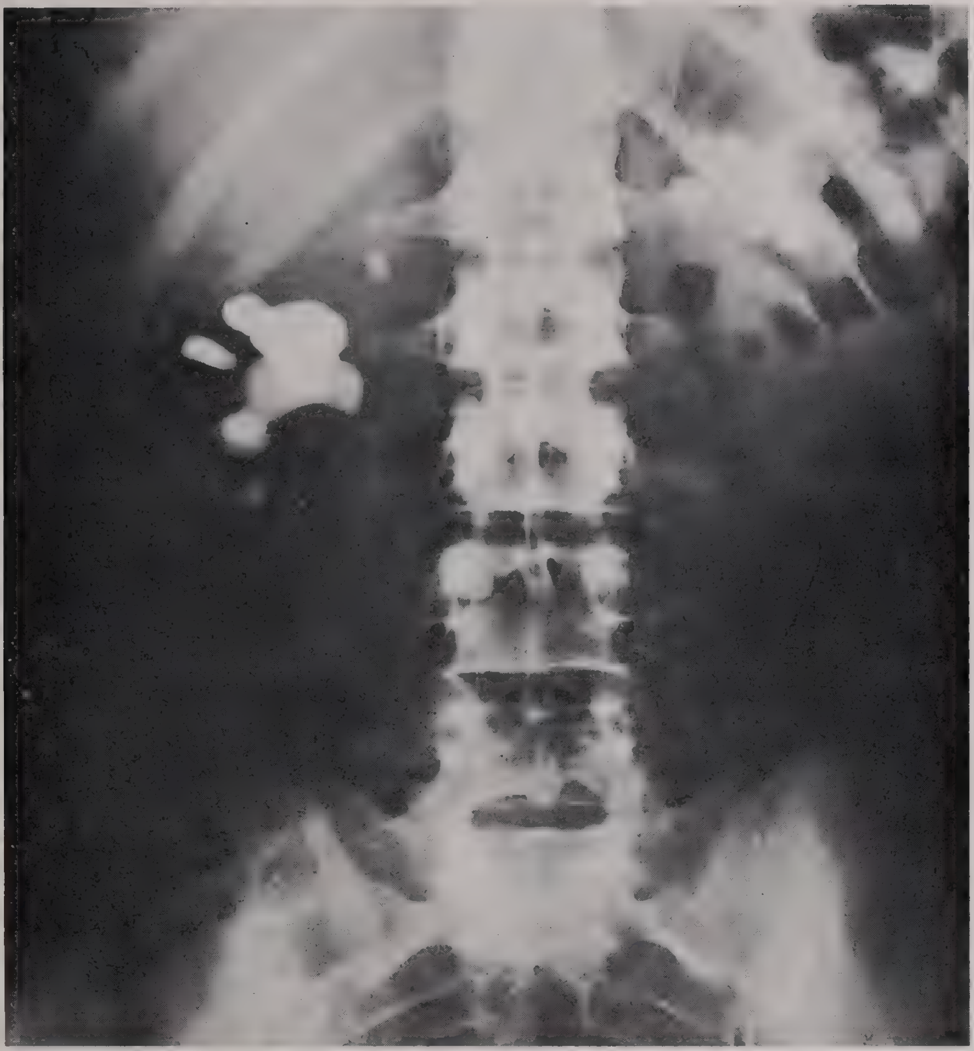
The Viewing Box



This 22-year-old white female was hospitalized because of weakness, nausea and vomiting. The past history revealed recurrent episodes of hematuria and renal colic secondary to urinary calculi since age 15. Three of nine siblings had urinary tract disease, one of whom developed urinary calculi.

Roentgen examination of the abdomen (Figure 1) demonstrated bilateral stag horn calculi plus numerous foci of renal parenchymal calcification in each kidney. The radiologist's differential diagnosis included:

1. Chronic glomerulonephritis or pyelonephritis.
2. Hyperparathyroidism.
3. Sarcoidosis.
4. Renal tubular acidosis.
5. Idiopathic hypercalcemia.
6. Hypervitaminosis D.
7. Primary hyperoxaluria.
8. Medullary sponge kidney.

What is your diagnosis? (See next page)

Diagnosis: Primary hyperoxaluria.

Primary hyperoxaluria is characterized by progressive bilateral calcium oxalate nephrolithiasis and nephrocalcinosis. A continuously high oxalate excretion is noted in the urine. The disorder usually begins in early childhood and leads to death from renal failure in childhood or early adult life.

Etiology is thought to be a metabolic defect leading to overproduction of oxalate. This condition has a familial incidence, but a definite hereditary pattern has not been established.

The roentgen picture consists of bilateral oxalate nephrolithiasis and nephrocalcinosis. Intravenous pyelography may be normal or demonstrate non-visualization secondary to calculus obstruction or renal failure. Radiolucent areas in long bone may signify deposition of calcium oxalate crystals.[3,4] The diagnosis of primary hyperoxaluria should be considered in all cases of nephrolithiasis and nephrocalcinosis noted in the first and second decades but particularly in a young child with a positive family history and without a demonstrable abnormality of calcium metabolism.

The patient presented had all the features of primary hyperoxaluria. A persistently high urinary oxalate excretion had been present since age 17. Onset at age 15 is somewhat unusual, as most reported cases note onset prior to five years of age.

To the Student

To the student I would say, that however plain and simple may be our teaching, he must expect to forget much which he follows intelligently in the lecture-room. But it is not the same as if he had never learned it. A man must *get* a thing before he can *forget* it. There is a great world of ideas we cannot voluntarily recall, — they are outside the limits of the will. But they sway our conscious thought as the unseen planets influence the movements of those within the sphere of vision. — Oliver Wendell Holmes

To Remove a Bone from the Throat

As Jesus Christ drew Lazarus from the grave, and Jonah out of the whale, thus Blasius, the martyr and servant of God, commands, 'Bone come up or bone go down.' — Aetius (6th century A.D.)

The Tobacco Tyrant

Much smoking kills live men and cures dead swine. — George Prentice

. . . NOTHING, THAT IS,
EXCEPT THE SEDATIVE-ANTISPASMODIC
BENEFITS OF

DONNATAL®

There's nothing quite like a vacation to ease the pressures of the modern, "workingday" world. And for the patient who can't get away from it all, there's nothing quite like Donnatal to relax stress-induced smooth muscle spasm. For 31 years it has been the antispasmodic-sedative most often prescribed for relieving functional disturbances of tone and motility of the gastrointestinal tract.

belladonna alkaloids in optimally balanced ratio

In Donnatal, natural belladonna alkaloids are rationally balanced in a specific, fixed ratio that provides "the greatest efficacy with the smallest possible dose."[1] They avoid the clinical uncertainties of the variable tincture and extract of belladonna, and are considered superior in range of action to atropine alone.[2] Furthermore, they are generally recognized as being more effective than the synthetics for relieving visceral spasm.

phenobarbital for sedation

Years of clinical use have established phenobarbital as one of the most efficient and highly regarded sedatives. In fact, for general sedation it is the drug of choice.[3] In Donnatal, phenobarbital potentiates the spasmolytic effects of the belladonna alkaloids, lessening emotional tensions and checking the neurogenic impulses that trigger GI disorders.

more than 24 indications in PDR

Donnatal has withstood the test of time to become the classic sedative-antispasmodic because of its unsurpassed effectiveness, safety, economy, uniformity of composition, and dosage convenience. Its widespread acceptance and usage by the profession can also be attributed to its versatility in treating disorders characterized by smooth muscle spasm. There are more than two dozen distinct and separate indications for Donnatal listed in the current PDR.

IN EACH TABLET, CAPSULE, OR (5 cc.) OF ELIXIR

atropine sulfate	0.0582 mg.
hyoscine hydrobromide ...	0.0195 mg.
phenobarbital	(3/4 gr.) 48.6 mg.

(warning: may be habit forming)

BRIEF SUMMARY: Blurring of vision, dry mouth, difficult urination, and flushing or dryness of the skin may occur on higher dosage levels, rarely on usual dosage. Administer with caution to patients with incipient glaucoma, or urinary bladder neck obstruction. Contraindicated in acute glaucoma, advanced renal or hepatic disease, or a hypersensitivity to any of the ingredients.

Taking an ECG?

Complete the clinical picture
with **a heart sound recording**

...made on your 500 VISO when you take the ECG

Increase your knowledge of cardiac condition with the valuable *additional* information provided by heart *sound* recordings. With this new Sanborn Heart Sound Amplifier clipped to the front of your 500 VISO* you can immediately obtain clear, sharply defined, graphic records — which identify the *location, intensity* and *duration* of the sounds and murmurs within the cardiac cycle. Even in the presence of complex arrythmias, marked tachycardias and other conditions which may complicate or prevent accurate auscultation by stethoscope alone, a definitive record of diagnostic quality can be obtained with this new instrument. Frequency cutoffs of 50, 100, 250 and 500 cps can be switch-selected to separate murmurs which might otherwise be masked by other heart sounds. As an electronic stethoscope, all sounds from 50 to 2000 cps can be heard at normal or amplified levels.

This precise Sanborn amplifier has convenient controls for recording the ECG, PCG, or ECG superimposed on the PCG . . . Cutoff Frequency . . . Audiophone Volume . . . and Sensitivity. Complete with contact microphone, cable and Audiophone (for use as an electronic stethoscope), Model 1506A is $450 f.o.b. Waltham, Mass. (continental U.S.). For more information, use the convenient coupon below. Sanborn Division, Hewlett-Packard Company, Waltham, Mass. 02154. In Europe, Hewlett-Packard S.A., 54 Route des Acacias, Geneva.

**or almost any other ECG with a 50 mm/sec. chart speed.*

Fracture–Trauma Conference

Orbital Floor Fractures

Swollen ecchymotic lids often mask the clinical picture of severe orbital injury. Since a black eye is so often associated with more severe head and body injuries, it may be neglected because it is "only a black eye."

The orbital rim consists of three bones: the frontal bone, the zygoma, and the maxilla. Immediately behind these heavy firm bones are some paper-thin, easily fractured bones. Fractures of these orbital bones may be clinically divided into two types: the external or rim fractures and the internal, blow-out fractures. A third not too uncommon group would combine the two.

Etiology of Orbital Floor Fracture

The orbital floor fracture was only recently explained in an interesting experiment by Converse and Regan[3] in which they placed a ball on the closed lids of a cadaver and struck the ball firmly with a hammer. On dissecting the orbit they found only a depressed comminuted fracture of the floor of the orbit. Next they exenterated a cadaver orbit, placed the ball on the orbital rim and struck it repeatedly with the same force as before. The floor of the orbit did not fracture—nor, for that matter, did the orbital rim. It is postulated then that the floor is fractured by the sudden increase in orbital pressure by the backward displacement of the globe. Interestingly, this backward "give" by the globe and the resultant floor fracture often protect the eye from serious damage such as rupture, choroidal tears, and intraocular hemorrhage.

Clinical Features

The clinical findings of a fracture of the floor of the orbit (besides the ecchymotic lids) may consist of any or all of the following:

Enophthalmos

The volumetric content of the orbit is increased by the depression of the floor, allowing the globe to rest deeper in the orbit — and sometimes lower in the socket. The vertical displacement may be more marked than the enophthalmos.

Continued

Ptosis May be Seen

This is not due to a levator palpebrae weakness but, because the globe is enophthalmic, the upper lid can hang down further on the eye (Figures 1 and 2).

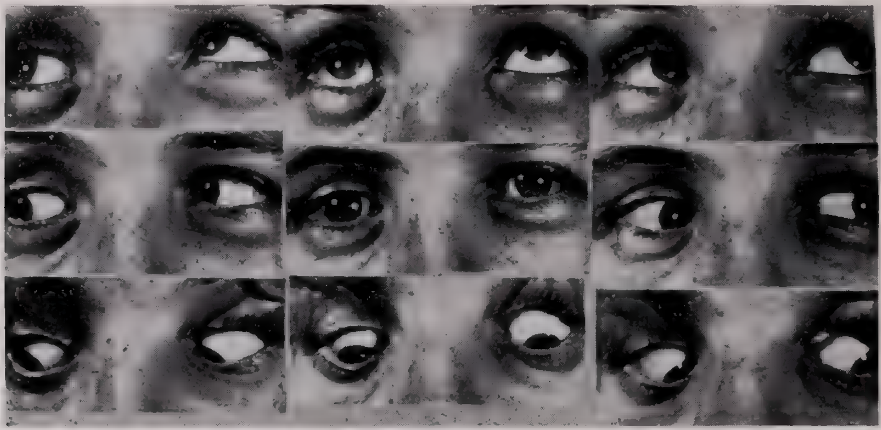

Fig. 1 — Pre-op fracture of floor of the orbit with incarceration of orbital contents. Note depression and pseudo ptosis of the left eye (most easily seen in straight-ahead gaze). There is also marked limitation of up gaze in the left eye.

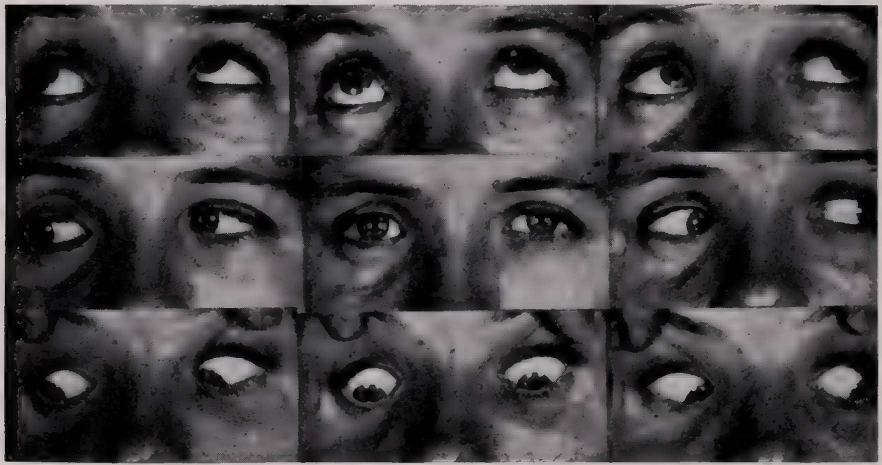

Fig. 2 — Post-op view — The floor of the orbit has been restored, with a normal cosmetic appearance and full ocular motility.

Limitation of Ocular Movement and Diplopia

These are usually due to the incarceration of the orbital contents, especially the inferior rectus and the inferior oblique into the fracture. There is usually limitation in up-and-down gaze, with diplopia in the up-and-down fields and single vision in the straight-ahead gaze.

Hypesthesia or Anaesthesia of the Cheek

When this occurs, it is due to trauma to the infraorbital nerve which passes through the floor of the orbit.

Diagnosis

Diagnosis of this fracture is by the clinical and x-ray pictures. The usual anteroposterior and lateral views are virtually useless in establishing the diagnosis. A Waters view is essential. On taking this x-ray, the head is tilted backward so that the tip of the nose and chin touch the film carrier. This orients the floor of the orbit in a plane perpendicular to the film and makes a depression of the floor easier to see. This view also rotates the sphenoid ridge below the level of the orbital floor, giving a good unobstructed view of the entire rim and floor.

The Orbital Rim

Fracture of the orbital rim may occur in any segment but occurs most frequently in the lateral and inferior rims. This fracture is always caused by direct trauma, usually from a fist or elbow, sometimes from the toe of a shoe and, with increasing frequency, from auto accidents.

The Zygoma

The zygoma is a strong dense bone which rarely fractures. Rather it separates at its sutures with the adjoining bone and also cracks in the arch, resulting almost invariably in three fractures: (1) At the zygomatico-frontal suture, (2) At the zygomatico-maxillary suture, and (3) In the arch. The bone is usually displaced inferiorly and rotated.

The Clinical Findings in Orbital Fractures

Flattened Malar Eminence

This is very disfiguring if left unrepaired, causing a rather easily noticed facial asymmetry.

Palpable Fracture

If there is not too much hemorrhage in the lids the fractures at the suture lines are easily palpated. With even a little zygomatic displacement and rotation, a "step-off" can be felt at the zygomatic maxillary suture.

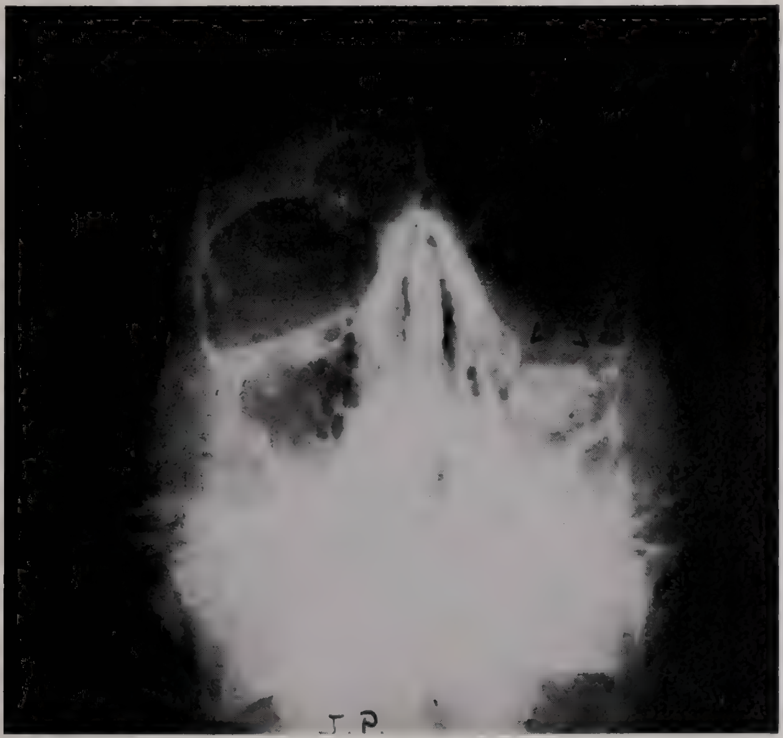

Fig. 3 — Waters view of an orbital rim fracture. Note the separations in the lateral and inferior rims. The underlying antcum is hazy because of hemorrhage.

Continued

Anaesthesia

Over the distribution of the infraorbital nerve anaesthesia may be found. This occurs because the fracture often extends through the infraorbital foramen, damaging the nerve.

Difficulty in Opening the Mouth Wide

This is due to the fracture of the zygomatic arch. There is sometimes an inward displacement of the arch, narrowing the temporal fossa, and impinging on the coronoid process of the mandible.

The diagnosis is easily made by the typical clinical picture and visualization of the fractures by x-ray (Figure 3).

Therapy

In the management of orbital injuries the following goals should be kept in mind: (1) Replacement of bony parts with restoration of facial symmetry; (2) Maintenance of ocular motility without diplopia; (3) Maintenance of jaw function and proper occlusion; (4) Treatment not delayed beyond two to three weeks when fibrocalcification of the wound begins.

The Orbital Floor

Treatment of an orbital floor fracture can be accomplished in several ways. It can be approached from below via a Caldwell-Luc type antrostomy. With this approach the floor of the orbit is digitally elevated and the position maintained by an antral pack or balloon. However, if an extraocular muscle is incarcerated between fragments, it will remain tightly fixed, and limitation of ocular rotation will persist. For this reason, I prefer a transorbital approach in which an incision is made in the lower lid at the level of the orbital rim. Periosteum is elevated off the floor, the fracture is located, and the incarceration freed. The floor can then be supported by overlaying it with autogenous bone, silicon or polyethylene plate, gelfilm plate or tantalum mesh or plate.

The Zygoma

Fractures and displacement of the zygoma can also be attacked in several ways. The bone can be elevated by the use of a transoral bar through the mouth beneath the zygomatic arch. It can also be elevated via an incision through deep temporal fascia from above the arch. Neither of these methods utilizes interosseous wiring. I prefer an open approach via the lateral rim over the fracture at the zygomatico-frontal suture. Holes are drilled above and below the fracture site, always entering posteriorly into the temporal fossa, rather than into the orbit. The zygoma is elevated by a malar hook or towel clip and the interosseous wire tightened. The zygoma usually stays in place without further wiring.

Conclusions

Simple black eyes may mask serious injury to the underlying bone. As the fractures may cause severe functional limitation, prompt therapy is urged.

Tumor Conference

Recurrent Thyroid Nodule Following Subtotal Thyroidectomy

The differentiation between Hurthle cell adenoma of the thyroid and Hurthle cell carcinoma often can be made only if it is known that there are no metastases. Hurthle cell carcinoma of the thyroid is not commonly seen. Although this particular type of thyroid is slow growing,[1] nonetheless, it grows both by direct extension and by metastasis and may eventuate in the death of the patient if unchecked by surgery or if preempted by death in some other manner.[2,3]

In many ways it is similar to papillary carcinoma of the thyroid. The mortality from papillary carcinoma of five years is quite low. Unfortunately, if followed long enough, a significant number of these patients can be shown to have died from their disease.[4] Even Crile, a strong advocate of suppressive hormone therapy, has pointed out that hormone-sensitive papillary carcinoma can over a period of time change into a highly malignant anaplastic* tumor and that all possible tumor in the cervical area that can be removed should be removed.[5]

The incidence of serious complications following a [straight-forward] thyroid lobectomy varies of course, but is, in fact, quite low if the surgery is performed meticulously in a bloodless field. This is the rationale that surgeons use to justify the removal of a rather large number of benign nodules. Let us ignore for the sake of this discussion the elimination of a sometimes symptomatic, worrisome lump to the patient. Surgeons and internists both get a somewhat skewed exposure to thyroid nodules, for both get a highly selected group of patients. The patient with a hard, painful, rapidly growing lump in the thyroid area often will go directly to a surgeon, whereas the patient with a soft barely palpable lump perhaps would consult his internist or general practitioner first. Nonetheless, if the criteria of malignancy are closely adhered to, as shown in large cancer centers, the diagnostitian can predict benignancy with an error as low as 2%.[6] When the incidence of morbidity and mortality of thyroidectomy, although admittedly low, is compared with this figure it does give some reason for being selective in operating upon thyroid nodules.

The incidence of serious complications following recurrent thyroid gland dissections is significant, and it is for this reason that recent emphasis has been on a complete lobectomy being done at the first sitting when

---

*See Test Your Word Score Page 607.

Continued

the surgery is for a nodule. If such an operation has not been performed a recurrence of nodularity can occur, and the recurrence may be a different pathological entity, as the following case illustrates.

Case History

A 76-year-old female was admitted to the Hennepin County General Hospital for the evaluation of a mass in the right side of her neck. Thirty-five years previously she had had a subtotal thyroidectomy for hyperthyroidism. Twenty years prior to admission she had had a second thyroid operation to further control a recurrence of her hyperthyroid symptoms.

For the past twenty years she has been followed in the medical clinic. Ten days prior to admission a well defined mass in the region of the right lobe of the thyroid gland was discovered upon examination and she was admitted for evaluation. Her PBI was 8.6 mgm%; the BMR's were +17 and+23, and a I^{131} scan revealed no concentration in the area of the mass, but pickup was noted over the isthmus of the gland. No palpable cervical adenopathy was detected and a chest x-ray revealed no evidence of metastases. Surgical removal was recommended because the mass was well-defined, apparently rapidly growing, and nonfunctioning on the I^{131} scan.

Exploration of the neck revealed considerable scarring, and after some difficulty the recurrent laryngeal nerve was identified on the right side. No identifiable parathyroid tissue was discovered. A clean lobectomy was performed, removing the remaining isthmus as well. Frozen-section diagnosis was Hurthle cell carcinoma but with a capsule. Final diagnosis was Hurthle cell adenoma because no blood vessel involvement nor capsular invasion could be demonstrated. (Figures 1 and 2). The patient recovered well from her surgery with no voice problem and fortunately no evidence of parathyroid deficiency.

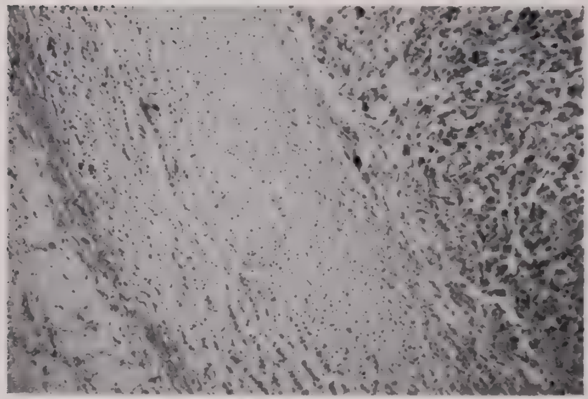

Figure 1

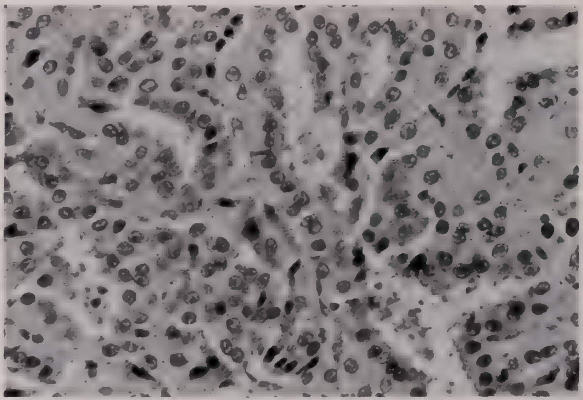

Figure 2

Discussion

This case demonstrates the point that the physician can not allow himself to be complacent in the evaluation of a thyroid nodule simply because he has prior evidence of a nonmalignant disease entity. He should evaluate a new nodule separately and with care. Whether or not he uses the I^{131} scan depends on personal preference. It would seem that its greatest use would be in proving functioning thyroid tissue in a nodule which the physician feels is benign from his own examination.

Nodules which are firm, fixed, or have shown rapid growth should be removed without delay. To this list should be added any nodule associated with cervical adenopathy or any nodule with associated hoarseness, dysphagia, or persistent cough.

Neurological Conference

Management of Cerebrovascular Insufficiency*

Cerebrovascular disease is rapidly being recognized as a condition for which numerous therapeutic procedures and improved care are available. In extracranial insufficiencies involving the carotid circulation, an endarterectomy will often prevent an impending cerebral infarct. Anticoagulation also may provide a greater margin of safety against such a catastrophe when surgically inaccessible vessels are the cause of cerebrovascular insufficiency. Of equally great importance is the fact that a more optimistic attitude towards "stroke" patients who have developed a physical impairment such as hemiparesis or hemiplegia is appearing. To supplement physical therapy, speech therapy and vocational rehabilitation, education of the patient's family and friends concerning their relationships with the patient offers great potential for improving the happiness of a handicapped patient.

Doctor Louise Town*

A 52-year-old former real estate salesman was seen at the University Medical Center Clinics for the first time on July 7, 1965, complaining of the loss of use of his left arm, trouble with his speech, and dragging of his left leg. His present illness began in 1960 when he awoke one morning and found that he had difficulty talking and trouble writing with his right hand. Within a few hours his function had returned to normal. Subsequently, after consulting with his doctor, he was treated for high blood pressure. Repeated episodes of difficulty in talking occurred during the succeeding years. On these occasions, however, he developed weakness of the left side of his face, drooling from the left corner of his mouth and dragging of his left foot. The duration of each episode varied from one hour to as long as one day. During the past nine months he has had approximately 15 such attacks. Progressive motor weakness has developed in the left side of his body, including rather severe involvement of the left

Defoe and Dr. Charles Branthaver in Pediatrics and Dr. Robert Soll, in Adult Neurology.

*Student doctor, University of Minnesota Hospitals.

Continued

arm. His memory has gradually deteriorated and his ability to think has slowed considerably. At the present time he is depressed and cries easily. A weight loss of 20 pounds has occurred over the past nine months.

His significant past history includes two whiplash injuries in the last five years. Extensive hypertensive disease and numerous strokes have characterized his family history. There has been no history of diabetes or heart disease, however.

Physical Findings

During physical examination the patient had difficulty following directions and was generally noncommunicative. His blood pressure was 160/90 mmHg.; his pulse was 96 per minute and irregular; and his respirations were 12 per minute. Positive findings on general physical examination included arteriovenous nicking in the fundi, an increased pulsation of the right carotid artery compared to the left, and a soft bruit over the left carotid near the angle of the mandible. Neurological examination revealed a left central facial palsy and a left hemiparesis characterized by a rather marked spasticity and flexor contractions of the left upper extremity. There were positive Hoffman, Mayer and Babinski signs associated with hyperactive deep tendon reflexes on the left side, with functional strength significantly decreased in the left hand. The patient was able to walk, although paresis of the left lower extremity slowed his gait considerably.

Laboratory Evaluation

Laboratory evaluation was within normal limits with the exception of a three-hour post-prandial blood sugar which was 139 mg. per cent; however, a glucose tolerance test subsequently was found to be normal. Skull films revealed evidence of calcification within the carotid siphon and choroid plexus. Degenerative changes were present in the cervical spine, and calcium deposition was also noted within the carotids bilaterally on cervical spine films. The electroencephalogram revealed evidence of diffuse slowing predominantly over the right hemisphere. Our initial impression was that the patient had cerebrovascular insufficiency secondary to carotid occlusive disease.

The patient was admitted to the University Hospitals on July 31, 1965, for angiographic studies and consideration of vascular surgery. These studies were performed on the right and left carotid and vertebral arteries. Significant narrowing by arteriosclerotic plaques was found near the origin of both the right and left internal carotid arteries; in addition, an irregularity of the intradural portion of the left internal carotid artery and left anterior cerebral artery was noted. Considerable narrowing at the origin of the right vertebral artery was present.

Dr. Robert Soll*

According to the history the right hand was involved initially with speech in 1960, although subsequent episodes apparently have involved primarily his left side. Consequently, the history alone would make one suspect that bilateral disease was present. This would be a more likely explanation for his speech difficulty, since speech dominance is in the left cerebral hemisphere in 90% of cases, regardless of whether the patient is right or left-handed.

*Neurologist, University of Minnesota Hospitals.

Intellectual Function

In a short interview preceding the examination, I realized that any test utilizing verbal interaction would probably produce little results; therefore, I approached him with the Peabody Picture Vocabulary Test, which consists of a series of pictures grouped according to progressively increasing difficulty in interpretation. With this test the examiner pronounces a word and the patient is asked to point to one of the pictures corresponding to the word. In this way we obtain an estimate of a person's intellectual functioning. On this particular test the patient received a raw score of 89 correct, placing his estimated IQ at about 78. Although we have no previous base line with which to compare these results, historically the patient's level of functioning would probably indicate that he has now suffered marked deterioration in his general capabilities.

Memory Defect

I then approached him with a few other tests in order to determine a possible memory deficit. On the Wechsler Memory Scale, which is a test to assess both recent and remote memory, he received a score of 61, whereas the average score is approximately 100; therefore, a significant memory deficit is also present. During this latter test I showed him a picture for 10 seconds and then asked him to draw what he saw. It was impossible for him to draw anything comparable to the designs. During this part of the test he suddenly said, "I can't see the drawing," although he apparently had been functioning very well before. It was at this point in the testing that the patient seemed to realize his deficit and manifested his frustration by retiring from the situation. A suggestion of this was brought out earlier in the interview when he abruptly stood up and said that he was going to get his wife, who apparently had been functioning as his spokesman since the onset of his speech difficulty. I called him back, telling him that we were interested in what he was able to do by himself, and he seemed to accept this. Nevertheless, he appears very sensitive about his deficiencies. Such an emotional reaction to realized loss of functioning has been noted among brain-damaged individuals and has come to be known as a "catastrophic" reaction.

Aphasia

In order to obtain an example of the aphasia that is present in this patient, I used a standard Binet Vocabulary Test, the only verbal test I used in this entire battery. I asked him to define the word "puddle," and he defined it as "a lot of this stuff that comes down out of the heavens makes a puddle." This is a classic aphasic response in that the patient has the concept in mind but is unable to give a precise synonym. To define the word muzzle, he said, "A bad dog." In the final test, the Porteus Mazes, he also did very poorly. The general conclusions from the entire battery of tests is that this man has suffered pronounced cerebral damage of a relatively diffuse nature, his problem of aphasia being his most severe difficulty.

Dr. Soll

It is possible that these tests may actually indicate a somewhat lower

Continued

result than is actually present. Some patients know what they are supposed to point at even though it may be simply a crude picture; however, they may be unable to do so because of an apraxia associated with a loss of speech and hearing.

Mr. James Gilbertson*

I might mention that the patient's performance on the Peabody Picture Vocabulary Test was good for the very easy items, whereas only when the pictures became more difficult did he have failures. In regard to the possibility of apraxia, however, I held the patient's jacket for him to put on when he was ready to leave and, when he had difficulty putting his good arm into the jacket, he turned about and attempted to put the jacket on backwards. This may be suggestive of apraxia.**

Miss Annie Laurie Baker†

At one time this man was very successful in business. He had been in the paint business for some time many years previously; but he eventually lost it. Then he went into new automobile sales and from that to selling second-hand cars. Failing in this venture, he lost almost all he had. Shortly after the onset of his illness he tried selling real estate but was unsuccessful. At that point, according to his wife, he lost confidence and became very depressed. He has remained so up to the present time.

There are two children in the family. The patient's wife is a high-strung individual, appearing frustrated by having to assume the responsibility for the family. This is of great concern to her, and she is hoping the children will eventually move back to be near their parents. For the last five years she has been the main financial support for the family, working as a secretary for the school nurse. Since this job employs her only ten months of the year, the family had a very hard time financially during the summer.

The daughter, a college graduate, is a social worker on the welfare board in another county; however, she is planning to leave this position and go to work for the welfare board in her home county in order to be with her parents. The son has had either two or three years of college. Apparently he has decided not to continue with his education. This is unfortunate, as he initially went to college on a scholarship. Since he is not returning to school, he has to repay this scholarship money which amounts to a considerable sum. The patient's wife remarked quite bitterly that, in order to keep the family going, she will probably have to sell the stock that an uncle left her. Social Security has been started for the patient, amounting to approximately $110 a month. The wife's income has been $200 a month, although she is now hoping to get a better job. Since they live in his mother's home, they fortunately do not have to pay rent. Although his mother is 83 years of age, she is very alert and is able to watch the patient during the day while his wife is working. I asked the wife what her husband did while she was at work, and she replied that he did nothing but sit on the davenport and watch television. As this is a family that is very confident and well known in their home town, I feel that once they become re-oriented they will be better able to carry on.

---

*Clinical psychology trainee, University of Minnesota Hospitals.

**See Test Your Word Score Page 607.

†Director, Social Service, University of Minnesota Hospitals.

Dr. Soll

Mr. Gilbertson, knowing these facts about the patient could you speculate what level of intellectual functioning he had prior to his illness?

Mr. Gilbertson

I would think he would probably fall in the average to bright-normal range which is 100 to 110 IQ, but his present IQ shows that he is now markedly impaired. His present inability to read prevented us from giving him the Minnesota Multiphasic Inventory test. However, he seems to have suffered marked cerebral damage, resulting in deterioration in all areas of intellectual functioning.

Dr. Soll

In this type of patient the electroencephalogram usually manifests diffuse slowing in both cerebral hemispheres; however, in this particular patient the slowing was more apparent in the right hemisphere, which would be consistent with his physical findings which are predominantly left-sided, involving the left arm and leg.

Interpretation of Pulsations and Bruit

In this patient the pulsation of the right carotid artery compared to the left was strikingly greater. Such a finding is often erroneously interpreted, as the first impression is that the artery having the stronger pulsation also has the greater bloodflow. However, this is true only when the obstruction in the involved artery is more proximal to the heart than the point at which one is palpating the artery. On the other hand, if the obstruction or narrowing is distal to the point which is being palpated, the artery will actually pulsate more strongly, even though the flow of blood through that artery is less. The presence or absence of a bruit, either in the region of a carotid bifurcation or in the area of the origin of the common carotid artery at the base of the neck, is also extremely important. Such a finding presents strong evidence for suspecting a partial obstruction of the artery. Absence of a bruit on the other hand could indicate that the artery is either completely patent or totally obstructed. Since this patient had a left hemiparesis, a very strong right carotid pulsation, and no bruit in the right carotid artery, we felt that it was quite possible that his right carotid artery was completely obstructed near the level of the carotid bifurcation. The presence of a bruit in the left carotid artery near the angle of the mandible suggested that the blood supply through this artery was insufficient.

Surgical Correction

Surgical correction of an occluded artery by means of endarterectomy is virtually impossible, because clot formation distal to the point of obstruction has usually already occurred. Nevertheless, since this patient's mental and physical capacity had deteriorated considerably, we felt that the possibility of surgery should be evaluated by angiography in order to prevent further damage. As Dr. Town has already reported, angiography was performed on this patient, revealing partial obstruction of both the right and left internal carotid arteries. Since complete occlusion has not already occurred, the possibility of benefiting from an endartectomy still exists.

Continued

Dr. Shelley Chou*

The fact that the patient is having difficulty with his speech in the absence of the other right-sided findings is not unusual, since the speech area in the brain is quite sensitive to arterial insufficiency. If anything is done it would be for the purpose of preventing further deterioration of his neurological condition, particularly his dysphasia. In analyzing the angiograms, the more involved side certainly seems to be the right side. There are reasons for operating on either side. After hearing the discussions about his aphasia, perhaps the left side should be approached first.

Dr. Soll

How competent must the contralateral carotid circulation be to assure an adequate collateral cerebral circulation during the operation?

Dr. Chou

We don't have a cross-circulation study in this case. This could have been accomplished by injecting one side and concomitantly compressing the opposite carotid in order to determine how much of the circulation crosses the mid-line into the opposite hemisphere. Assuming there is no cross-circulation from the left to the right side, the risk of surgery in this case would be markedly increased. In order to reduce the risk, we would have to use a temporary shunt in the form of a silastic tube to bypass the segment of artery that was being operated on.

Dr. Richard Magraw**

What indications do you use for recommending surgical intervention in these patients with cerebrovascular insufficiency? Is finding a bruit on a routine examination an adequate indication, or must a patient have a history of a transient episode of insufficiency associated with a temporary neurological deficit?

Dr. Chou

We do not operate on the basis of physical signs alone but prefer to consider patients and their symptoms. We perform surgery to prevent deficits from occurring or from becoming permanent. If a permanent deficit is present we would infer that some damage to the brain tissue has already occurred. A patient who presents a complete hemiplegia of three or four days duration would be a poor candidate for surgery, since the likelihood of recovering function would be small even though the circulation might be re-established. The best candidate, would be one with minor and transient ischemic symptoms; however, we would not perform surgery on a patient who had had only one minor transient episode. The surgery is major in character, and there certainly has to be a very adequate reason for it. There is also some controversy about doing angiography on such a patient since it involves an element of risk. Assuming that angiography is performed and a large plaque visualized in an artery, I think surgery would be justified.

---

*Associate professor, Neurosurgery, University of Minnesota Hospitals.

**Director, Comprehensive Clinic, University of Minnesota Hospitals.

Dr. Magraw

Is hemiparesis a fairly common occurrence in the course of doing an angiogram?

Dr. Chou

No, an angiogram generally is not risky, but there is a significant risk in the particular group of patients who have pre-existing disease in their circulatory system. Consequently, we are a little more careful with this type of patient. It is difficult to answer the question regarding how much improvement might be gained by surgery, because one operates on patients with various degrees of deficits. Some patients, curiously, have only mental symptoms or emotional lability. I would estimate roughly that 60% of patients will benefit by surgery. The mortality rate itself is not too high. We have had one patient who had a cerebral infarct prior to surgery and subsequently, following surgery, developed a hemorrhagic infarct and died.

Neurology student

How much reversal of this patient's mental deterioration might one expect if surgery was successful?

Dr. Chou

I think it depends on the type of mental deterioration present. If it is an episodic mental deterioration which could be explained on the basis of an ischemia one might expect a marked improvement. On the other hand, if a patient has shown progressive mental deterioration over a period of six months to a year, the likelihood for improvement is very small. It is interesting that 10% of our patients who have stroke symptoms have been found to have tumors.

Dr. Magraw

The Public Health texts state that the best measure of high quality health care being provided in an area is a preponderance of deaths from heart disease, cancer or stroke, with a minimal mortality from other causes. In years past many of us have been content to diagnose these so-called "strokes" and do nothing more. Now there is insistence that we do something more than simply diagnose and then write these people off as having had a stroke. A stroke is a "complication" of cerebral or extracranial vascular disease. In the next five or ten years we may become progressively more aggressive in attempting to prevent this complication.

Addendum

It was elected to attempt carotid endarterectomy on this patient; however, during induction of anesthesia prior to surgery, the patient had a temporary cardiac arrest and the surgical procedure was cancelled. The risk accompanying any further attempt to do surgery was considered too great. Subsequent therapy has primarily involved helping the patient's family prepare to care for him after his return home.

Athletic Injuries

Maxillofacial Injuries in Athletics

Because maxillofacial injuries are a form of head trauma, one should first ascertain if there has been unconsciousness. Obviously, if the patient has sustained a significant cerebral concussion, he must be evaluated from that standpoint as well as for his possible maxillofacial injuries.

Probably the most common injury in contact sports is the contusion to the nose, causing epistaxis. Often this is associated with a fracture of the nose. Gross distortion makes diagnosis simple, but it is not always possible to determine a nasal fracture without x-rays. If bleeding is troublesome on the scene, a small amount of vaseline packing in each nostril will usually afford adequate hemostasis until the patient can be brought to the doctor's office or Emergency Room.

Facial lacerations obviously require immediate surgical care, including the sometimes forgotten tetanus toxoid booster. Important avulsed tissue, such as pieces of the nose or ear, should be saved because they can sometimes be replaced if they are in good condition.

Pain along the mandible should alert one to the possibility of a mandibular fracture. Inspection of the mouth should be done with adequate light. Often there will be a tear in the gingiva between the teeth in the presence of a mandibular fracture. If a fracture of the maxilla is suspected, one should also test the stability of the upper teeth to see if there is any movement. Probably the most important diagnostic aid is to check the occlusion of the teeth; most jaw fractures will cause malocclusion. This is usually evident both to the examiner as well as to the injured person. It might be well to add that loose teeth should not be pulled out at the scene of the injury. Many times they will tighten up spontaneously and it may be many months before anyone can be sure that a tooth is irrevocably devitalized.

Fractures of the malar or cheek bone produce ecchymoses and edema of the eyelids. If the floor of the orbit is involved, visual signs, such as diplopia, will usually occur. Contusions in this area may also cause paresis of the ocular muscles, also causing blurred vision or diplopia. Fractures of the malar often manifest themselves initially by flattening of the cheek or a palpably jagged fracture line along the infraorbital rim. Fractures of the zygomatic arch should be suspected if the individual has difficulty opening his mouth.

The diagnosis of significant maxillofacial injuries can often be made on the playing field, but more subtle injuries usually require not only x-ray studies, but more careful evaluation in the relative quiet of a doctor's office or emergency examining room. Because of the potentially serious problems, such as malocclusion, unacceptable cosmetic results, or visual aberrations as a result of these injuries, it is well to have appropriate consultation early.

"All Interns are Alike"

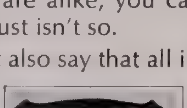
It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

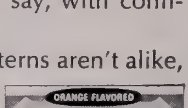
That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.





Medical Seminar

Malignant Neoplasms of the Nasopharynx

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

BECAUSE OF ITS insidious nature, cancer of the nasopharynx is commonly overlooked during its early stages and thus is one of the most lethal of neoplasms. This cancer constitutes from 0.3 to 0.4% of all forms of cancer and affects males three or four times more frequently than it does females. The cancer has been found in all age groups, from the very young to the very old, with a peak incidence in the fourth and fifth decades of life. The average age for males is 55 years while that for females is 49 years. The Chinese are said to be more commonly afflicted than are the other races.

Anatomic Considerations

Anatomically the nasopharynx extends from the base of the skull to the level of the free border of the soft palate. Its roof lies beneath the body of the sphenoid bone. The posterior wall is smooth and dotted with lymph patches; the lateral walls are largely occupied by the openings of the eustachian tubes. The posterior margin of each eustachian tube forms a prominent projection (torus tubarius) which is the inner extremity of the cartilaginous part of the eustachian tube. Between the posterior margin of the tubular orifice and the posterior wall of the nasopharynx lies the lateral pharyngeal recess or fossa of Rosenmüller. The anterior wall is formed largely by the choanae leading directly into the nasal fossae, while the floor is formed partly by the dorsal aspect of the soft palate.

The predilection of neoplasms for certain parts of the nasopharynx together with the special anatomic relations in this area account for much that is curious in the natural history of tumors of this region. The walls of the nasopharynx will not long confine a rapidly growing neoplasm which will soon spread to the adjacent oropharynx and nasal cavities. Those tumors, which spread chiefly by infiltration of neighboring regions, frequently extend to the cranial cavity, the orbit, or the parapharyngeal spaces. Metastatic spread to cervical nodes is common in nearly all types of nasopharyngeal cancer.

The important anatomic features concerned with the spread of nasopharyngeal cancer include the pharyngeal fascia, the relationships of the fossa of Rosenmüller, and the lymphatic drainage of the nasopharynx.

The Fascia

The pharyngeal fascia comprises the *pharyngobasilar fascia,* which is submucosal and is situated within the confines of the muscular walls of the pharynx, and the pharyngeal portion of the *buccopharyngeal fascia,* which is external or peripharyngeal. At the upper border of the superior constrictor muscle the two fascial layers fuse to form a single, dense, fibrous lamina which occupies the sinus of Morgagni. Below, the eustachian tube and the levator and tensor muscles of the soft palate lie between these two fascial layers. External to the buccopharyngeal fascia, the parapharyngeal space separates the pharynx from the mandible, parotid gland, and muscles of mastication. The fascial planes permit mobility of the eustachian tube and pharyngeal musculature, give support and direction to the

Continued

pharyngeal vessels, and form channels for the passage of tissue fluid and lymph.

A neoplastic process may follow these fascial planes; however, this is unusual. More commonly the lesion crosses this fascial barrier and invades the parapharyngeal space, which can be subdivided into three compartments. The prestyloid compartment comprises that portion anterior to the styloid process of the temporal bone and is bounded superiorly by the base of the skull, inferiorly by the submaxillary gland, and posterolaterally by the angle of the mandible and parotid gland. Within this compartment lie the internal maxillary artery, the lingual nerve, and the mandibular division of the trigeminal nerve. Invasion of the prestyloid compartment produces sensory disturbances in the areas supplied by the mandibular and lingual nerves, trismus if the pterygoid muscles are invaded, and depression of the soft palate if its muscles are involved. Upward extension in this compartment leads to intracranial invasion via the foramen ovale, foramen spinosum, or wing of the sphenoid bone. Posterolateral spread may involve the parotid gland with a resultant facial weakness or paralysis.

Posterior to the styloid process, the retrostyloid compartment contains the carotid artery, internal jugular vein, last four cranial nerves, and cervical portion of the sympathetic trunk. The clinical picture seen with invasion of this compartment includes Horner's syndrome and hemiparalysis of the soft palate, lateral pharyngeal wall, tongue, and larynx as well as sensory disturbances in these regions.

Behind the posterior wall of the pharynx and medial to the carotid sheath lies the retropharyngeal compartment. Few symptoms are produced by invasion of this space, although enlargement of the contained lymph nodes may cause compression of the carotid sheath with its contents and produce symptoms not unlike those seen with involvement of the retrostyloid compartment.

The Fossa of Rosenmüller

This fossa is a common site of cancer formation. Because of the local anatomic relationships cancer of this area has an opportunity for spread that is especially important. Dissemination laterally and posteriorly involves the prestyloid and retrostyloid regions and produces clinical evidence of involvement of the parapharyngeal space. Perhaps the most serious route of dissemination is superiorly through the base of the skull into the middle cranial fossa. The foramen lacerum is the most common point of entry, with or without invasion of the surrounding bony structures. Invasion by this route entails early destruction of the basilar cranial nerves in almost direct proportion to their proximity to the foramen lacerum and immediately adjoining cavernous sinus. Thus, cranial nerves III, IV, V, and VI may be affected jointly by a small lesion involving the cavernous sinus. In more advanced cases with extension along the floor of the middle cranial fossa, there may be involvement of the optic nerve, the orbit, or the anterior cranial fossa. Extension to the posterior fossa is rare, although possible. Other less common routes include an anterior dissemination to involve the nasal cavity, sinuses, and orbit.

The Lymphatic Drainage

Involvement of the regional lymph nodes is even more common than cranial nerve complications. Metastases may be bilateral in as many as 40% of the cases. As far as the clinician is concerned the most commonly involved nodes are the upper deep cervical nodes. The superior group is the most important, especially the jugulodigastric node and the nodes beneath the upper end of the sternocleidomastoid muscle. Less commonly involved are the nodes along the spinal accessory nerve and those associated with the transverse cervical vessels. It is unusual to see involvement of nodes in the anterior cervical triangle unless the tumor invades the oropharynx or parapharyngeal space or involves the floor of the nasopharynx. Distant metastases have been reported to the thorax, skeleton, central nervous system, and viscera but these are uncommon.

Symptoms

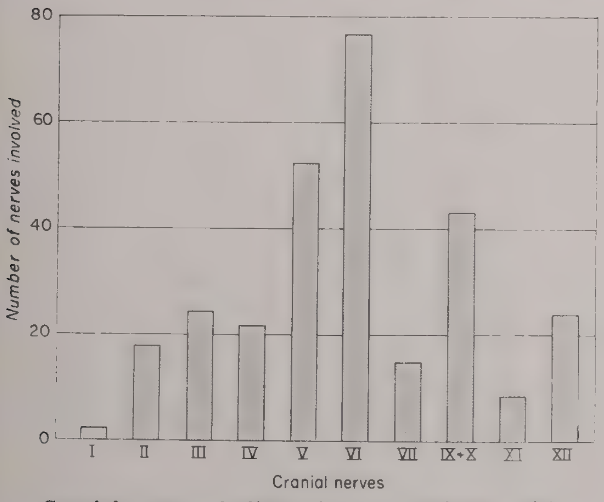
In a recent study,[1] 84% of the patients had generalized symptoms while 16% had primary neurologic complaints.

General Complaints

The most common general complaint was head and face pain, comprising 45% of the presenting complaints. This was nearly always unilateral, frequently with nocturnal exacerbations, and at times suggestive of a trigeminal neuralgia. Thirty per cent had otologic symptoms, including hearing loss, tinnitus, or a feeling of fullness or pressure in the ear. These symptoms nearly always resulted from a unilateral serous otitis media secondary to eustachian tube obstruction in the nasopharynx. Although glandular swelling in the neck was obvious on the initial examination in 70% of the patients, it was the major complaint in only 18% of them. Even less common (15%) were nasal symptoms including obstruction, postnasal discharge, and epistaxis.

Neurologic Complaints

The Figure gives the incidence of involvement of individual cranial nerves in a series of 286 cranial nerve lesions occurring in 111 patients with malignant lesions in the nasopharynx. Most commonly affected were the motor nerves of the eye and the trigeminal nerve. These are involved in what may be termed the petrosphenoidal syndrome. This syndrome is found with intracranial tumor extension via the foramen lacerum. In this region the trunks of cranial nerves II through VI are closely grouped and vulnerable to neoplastic invasion. The patient is ultimately left with a paralyzed, blind eye.



Cranial nerve findings in 111 patients with nasopharyngeal malignant tumors.
(From Thomas, J. E., and Waltz, A. G.: Neurological Manifestations of Nasopharyngeal Malignant Tumors. JAMA 192:95, 1965. By permission of the publisher.)

Pathways of Extension

Although there is no direct communication between the nasopharynx and the orbit, there are several pathways by which a neoplasm may reach the orbit. The first is intracranial extension via the superior orbital fissure. The other routes are extracranial, either by way of the inferior orbital fissure or the nasal fossa. Once the tumor has reached the nasal fossa it may continue toward the orbit either through the sphenopalatine foramen or by direct invasion through the ethmoidal air cells, which are poor barriers to neoplastic spread. Proptosis may occur, therefore, with or without paralysis of the oculomotor nerves. If the motor nerves to the eye are involved intracranially, the paralysis precedes the proptosis. If they are involved extracranially, the paralysis follows the proptosis.

Other cranial nerves may be affected as shown in the Figure. The olfactory nerve is perhaps the least often affected; nerves VII and VIII are only rarely involved. Although the last four cranial nerves lie some distance from the primary site, they are not infrequently involved extracranially.

The combination of cranial nerve defects most commonly found[1] was that involving nerves V and VI. Next in frequency was dysfunction of nerves IX, X, and XII. Several other combinations were observed less frequently and, in addition, there was a wide variety of cranial nerve lesions which followed no particular pattern. There are many eponymous syndromes relating to various combinations of cranial nerve lesions (Table 1), any of which may be seen with nasopharyngeal malignancy.

Pathology

Lack of agreement in classification, especially of the poorly differentiated tumors, renders comparative morbidity statistics unreliable. Histologically, the epithelium of the upper part of the nasopharynx is a pseudostratified, ciliated, columnar type with many goblet cells. Because of the character of the mucous membrane and its associated lymph-

TABLE 2

Classification of Malignant Tumors of the Nasopharynx

Subdivision	Remarks	Incidence (%)
Squamous cell carcinoma	Includes all degrees of squamous differentiation (grade 1 to grade 4)	19
Lymphoepithelioma	Includes all undifferentiated carcinomas whether lympho-epithelioma or transitional cell type	67
Lymphosarcoma		5
Others	Miscellaneous types including small cell, cylindroma, etc.	9

Modified from Scanlon, P. W.; Devine, K. D., and Woolner, L. B.: Malignant Lesions of the Nasopharynx, Ann Otol Rhin Laryng 67:1005, 1958.

oid and glandular structures, many different histologic varieties of tumor may be found. Table 2 gives the pathologic classification and incidence of malignancies of the nasopharynx from a Mayo Clinic study reported by Scanlon and co-workers.[2] Apart from the squamous-cell carcinomas of various grades, the presence of lymphoid tissue may give rise to lymphoma, while the presence of glandular elements may give rise to adenocarcinoma. In addition, any of the connective tissue sarcomas may be found. Metastatic tumors to the nasopharynx have been reported but are uncommon. Scanlon and co-workers[2] stated that lesions such as juvenile fibromas, chordomas, craniopharyngiomas, and plasmacytomas and, to a lesser extent, teratomas, hemangiomas, lymphangiomas, posterior choanal polyps, tuberculous retropharyngeal lymph nodes, or even pituitary tumors may resemble primary malignant lesions of the nasopharynx so closely that differentiation can be made only on biopsy.

Diagnosis

Every effort must be made to inspect the entire nasopharynx. Topical anesthesia frequently helps to control gagging. Another measure which at times may be useful consists of passing soft rubber catheters through each nostril into the nasopharynx and then back out through the mouth. A gentle tug on the catheters will then retract the soft palate forward and provide a good view of the nasopharynx. Digital examination may be helpful. Often a cotton swab passed over a malignant area will incite surface bleeding. Many examiners become proficient with the nasopharyngoscope, but this requires practice.

Biopsy

Nasopharyngeal biopsy is an extremely important diagnostic procedure. Biopsy of obviously involved or suspicious areas can be readily performed transnasally as an office procedure. Occasionally one encounters a case in which the clinical pattern suggests a nasopharyngeal lesion, but no obviously involved or suspicious site can be found in the nasopharynx. In these instances, multiple blind biopsies under general anesthesia may be successful in locating an elusive primary lesion. This technique is even more valuable if immediate frozen-section pathology reports can be obtained. On occasion, an excision of a metastatically involved cervical node may establish a diagnosis of malignancy; however, it is not recommended that these nodes be excised for biopsy purposes unless all other diagnostic routes have been exhausted.

X-ray Studies

Roentgenographic studies are frequently helpful. A lateral view may show a mass in the nasopharynx or an erosion in the sphenoid area. Perhaps the most important view is the stereoscopic view of the base of the skull, which may show unilateral decalcification in the petrosphenoidal region or enlargement of the foramen lacerum or foramen ovale on one side.

No attempt will be made to list the lesions which may simulate carcinoma of the nasopharynx; such a list would be so extensive as to be meaningless. Practically any single cranial nerve or any combination of cranial nerves as well as the cervical sympathetic nerves may be involved. Therefore, any patient presenting with an unexplained cranial nerve lesion or any of the cranial nerve neuralgias and all patients with a conductive hearing loss (especially unilateral) should undergo examination of the nasopharynx.

Treatment

The treatment of nasopharyngeal carcinoma is largely a radiotherapeutic problem, since operation alone is not curative.

Radiotherapy

Many of the tumors are radiosensitive; therefore, an attempt should be made at curative treatment. Palliative treatment is reserved for recurrent lesions or lesions associated with bilateral fixed nodes or distant metastases. The treatment of choice is supervoltage irradiation, with local radium application being used for localized recurrent lesions. Some institutions use prophylactic irradiation to the cervical regions bilaterally, while others prefer to treat the neck only when metastases are palpable.

Continued

There are certain technical considerations which add difficulty to radiotherapy in this region of the body. The nasopharynx is situated beneath the center of the base of the skull in close relationship with the brain and several of the special sense organs. Lederman[3] has pointed out that, of the related structures, the eye, the cerebrospinal axis, and the salivary glands are susceptible to radiation damage; but the auditory, vestibular, and olfactory organs and the pituitary gland are rarely injured.

Surgery and Irradiation

Recently a combined surgical and irradiation approach has been tried in certain cases of squamous-cell carcinoma with cervical metastases. This consisted of irradiation to the primary lesion with neck dissections where nodes were palpable; if necessary, bilateral radical neck dissections were done. The efficacy of this approach will have to await comparative statistical analysis.

Results of Treatment

Results of various studies indicate a 9.8[4] to 27.6%[5] survival rate. The two most important factors determining salvage rates are the type of the lesion and the extent of dissemination. The five-year survival rates with lymphoepithelioma and lymphosarcoma can be expected to exceed those with squamous-cell carcinoma by two or three to one. The importance of tumor dissemination is emphasized by one study[2] in which the five-year survival rate was 30% when the tumor was confined to the nasopharynx but only 15% when there was extension to regional nodes. The survival rate was 27% when the tumor had advanced superiorly and destroyed the floor of the middle cranial fossa or involved the cranial nerves. There were no five-year survivors when both types of metastatic spread were present. The over-all five-year survival rate was 17% in the series.

There is so much disagreement in classification and in reporting of results that, to date, comparative morbidity statistics are of little value. In an attempt to establish uniformity, a system of classification and staging has been proposed.[6] It is hoped that universal acceptance by clinicians of such a system will enhance cancer control through more accurate collection of data, more accurate evaluation of therapy, and better reporting of results. In this system, the TNM system, "T" refers to the tumor or primary lesion and its extent; "N" refers to regional nodes and their condition; and "M" refers to distant metastases. Each component is then subdivided, with numerical suffixes indicating the extent of involvement (Table 3). The tumors then can be classified into four stages, the essential features of which are summarized in Table 4.

A Stage I lesion is a small growth in the nasopharynx without cervical lymph node involvement or distant metastases. A Stage II lesion is more extensive locally but still without evidence of local or distant spread. The essential feature of a Stage III lesion is the presence of palpable cervical nodes that

TABLE 3

The TNM System of Classification for Carcinoma of the Nasopharynx

Definition of T Categories

T1	Tumor limited to one site in the nasopharynx (vault or lateral wall)
T2	Tumor extending into two sites (vault and lateral wall)
T3	Tumor extending beyond nasopharynx

Definition of N Categories

N0	No clinically palpable nodes
N1	Palpable cervical nodes; not fixed
N2	Palpable cervical nodes; fixed

Definition of M Categories

M0	Distant metastases absent
M1	Distant metastases present

TABLE 4

Summary of Clinical Stages of Carcinoma of the Nasopharynx Based on the TNM System

Stage	T	N	M
I	T1	N0	M0
II	T2 or T3	N0	M0
III	T1, T2, or T3	N1	M0
IV	T1, T2, or T3	N2	M0
		N0, N1, or N2	M1

are not fixed. Any degree of primary involvement may be present in the nasopharynx; however, there is no distant spread. A Stage IV lesion is one in which there are fixed cervical node metastases or distant mestastases or both. It must be emphasized that stage classification is a clinical one and is based on the anatomic extent of the disease at the time of the initial examination. It is intended that stage classification will group together patients who have the same degree of disease and who should have a similar prognosis.

The results of field trials[6] in which 371 carcinomas of the nasopharynx were studied demonstrated that survival of patients with nasopharyngeal carcinoma can be correlated with the proposed stages. There was a 60 to 76% five-year survival with Stage I lesions, 38 to 41% with Stage II, 29 to 34% with Stage III, and only 17 to 25% with Stage IV. At first glance some of these values may seem high when compared with many of the previously reported studies. However, when one considers the insidious nature of the tumors, it must be realized that the majority of the reported series must comprise Stage III or Stage IV lesions. For example, the study by Thomas and Waltz[1] contained only tumors with cranial nerve involvement and these would all have been Stage III or Stage IV. The survival rate in their study was 24%. Likewise, in the study by Scanlon and co-workers[2] the tumors would also have been largely Stage III and Stage IV lesions, and their results show a 17% five-year survival rate.

Summary

Carcinoma of the nasopharynx comprises from 0.3 to 0.4% of all malignant tumors of man. The peak incidence is in the fifth and sixth decades of life, with a male preponderance of approximately 3:1. A variety of histologic cell types can undergo malignant degeneration in this area; perhaps the most common malignancy is lymphoepithelioma. In many instances the point of origin is difficult to determine at the time the tumor is discovered. The fossa of Rosenmüller and the vault are the most commonly affected areas. Tumors of the sarcoma group spread more readily to regional nodes, occur in younger age groups, and are more sensitive to treatment than are tumors of the squamous-cell group.

When the tumor extends through the foramen lacerum, cranial nerves V and VI are most frequently involved. When extension is in a posterolateral direction through the parapharyngeal space, cranial nerves IX, X, XI, and XII and the cervical sympathetic nerve are more commonly affected. However, involvement of any combination of cranial nerves may occur.

The results of treatment are uniformly poor, with a five-year survival rate of less than 25%. The more important features in determining survival are the type of tumor and the extent of spread. While the results are not encouraging, it can be hoped that further refinements in technique, earlier diagnosis, and a better understanding of the biologic variations involved will lead to a significant improvement in the survival rate.

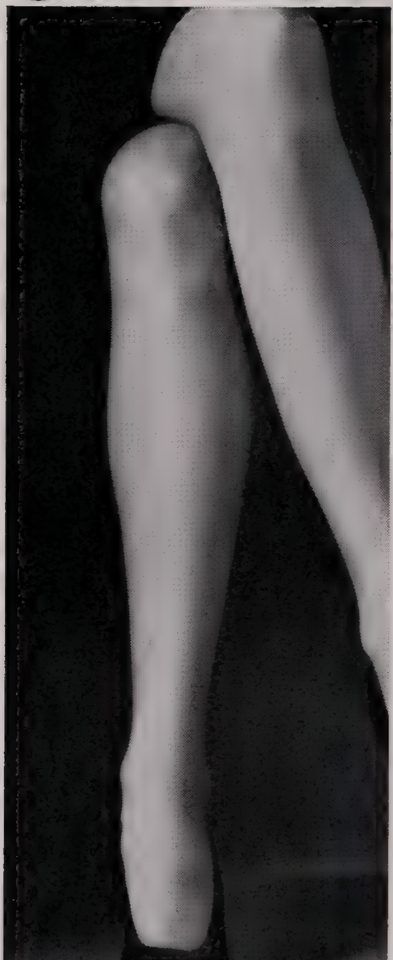
You prescribe elastic stockings.
She won't wear them.
Now what?

Ultreer™



Elastic Stockings so sheer they look like support hose. Both Ultreer and support hose are sheer, shapely, cool and comfortable. But that's where the similarities end. New Ultreer fits firmly and evenly over the entire leg. Gives true therapeutic compression necessary to relieve varicose veins and other leg disorders. They provide the therapy you prescribe. The fashion and economy she demands.

Ultreer stockings have a new low price. So low, she can afford two pairs of Ultreer instead of one pair of regular elastic stockings. There'll be no disagreements there. Ultreer stockings are as comforting to her purse as they are to her legs. New Ultreer are the elastic stockings doctors and women can agree on.

BAUER & BLACK SUPPORTS DIVISION

Clinical Path Conference

Systemic Torulosis in a Diabetic Patient*

This 69-year-old negro female began having episodes of confusion, disorientation and slowness of thought five months prior to admission to Hennepin County General Hospital on August 20, 1963. Recurrent headache, nausea and vomiting had necessitated her admission to a private hospital in early July, 1963. A two-year history of fluctuating cervical adenopathy was elicited, and a scalene node biopsy was reported as showing noncaseating epithelioid granulomata. Thereafter, the patient became somnolent and was noted to have a stiff neck. No seizures or syncopal episodes were reported; however, the family physician was said to have suspected a brain tumor.

There was a 12-year history of adult type diabetes mellitus treated with 25 units of NPH insulin. The diabetic state had been well controlled until recent weeks when the patient's fluid and food intake diminished, and a 15-pound weight loss had occurred.

The onset of deep coma led to her transfer to Hennepin County General Hospital. When the patient was given an infusion of 300 cc. of 10% dextrose in water and promptly awakened, the possibility of a hypoglycemic reaction was considered. Her blood sugar was reported to be 129 mg.%.

Physical Examination

The patient appeared as a confused, lethargic, combative, elderly negro female. Her verbal responses to questions were inappropriate, and she was markedly disoriented. The blood pressure was 170/90 mm. of mercury; the pulse 90 per minute; the respiratory rate 18 per minute, and the temperature 100° F. Optic fundi showed no evidence of papilledema. Slight nuchal rigidity could be demonstrated. The lung fields were clear to percussion and auscultation. A Grade II systolic murmur was present at the cardiac apex. The abdomen was soft and doughy, and did not appear to be distended. The liver, spleen, and kidneys were not enlarged to palpation. The bowel sounds were not accentuated. Costovertebral angles were nontender. The turgor of the skin suggested severe dehydration. Neurological examination showed decreased sensation on the left side of the body as tested by pinprick. The deep tendon reflexes were slightly enhanced on the

---

*See Test Your Word Score Page 607.

Continued

left. Bilateral Babinski toe signs were present, the right being more marked than the left.

Laboratory Studies

The hemoglobin was 11.1 grams %; the white blood cell count was 10,100 per cu. mm. with 88% neutrophils and 12% lymphocytes. Urinalysis revealed a specific gravity of 1.015 with 4+ glycosuria and no proteinuria. Microscopic examination of the urinary sediment showed occasional red blood cells and pus cells. A urine culture grew out greater than 100,000 colonies per cc. of proteus species and gamma streptococci. A sputum culture showed a mixed flora consisting of pseudomonas, proteus, E coli and Klebsiella species. The erythrocyte sedimentation rate was 121 mm. per hour (Westergren). A BUN was 14 mg.%. The serum sodium was 131 mEq/L; the serum potassium 4.2 mEq/L; the serum chloride 86 mEq/L; and the CO_2 combining power 26 mEq/L. Stool guaiac tests were weakly positive. The blood VDRL was positive only with undiluted serum, and the blood Hinton test was 3+. The Reiter protein complement fixation test was non-reactive. Tests of dermal sensitivity with coccidioidin, blastomycin and histoplasmin were non-reactive in 48 hours. A 1:10,000 Mantoux test was negative.

Lumbar Puncture

Shortly after admission, the patient's neurologic status further deteriorated. On lumbar puncture, the spinal fluid was slightly turbid and revealed a cell count of 62 per cu. mm. with 86% mononuclears. The spinal fluid protein was 33 mg.% and the sugar 100 mg.%. The colloid gold curve was reported as 1 4 4 3 3 2 1 0 0 0. Budding yeast-like organisms were demonstrated in the spinal fluid on an India ink preparation. Spinal fluid culture revealed Cryptococcus neoformans. The EEG was abnormal, showing diffuse slowing of rhythm.

Progress

The patient was begun on Amphotericin B, 50 mg. daily, given intravenously to run over a period of two to six hours. Her sensorium and neurologic status deteriorated rather rapidly during her hospital course. Therapy was instituted with penicillin and Kanamycin because of a left lower lobe pneumonia. The serum calcium was 8.4 mg.% and the serum phosphorus 2.2 mg.%. Serum alkaline phosphatase was 6.5 KA units. The blood sugars fluctuated between 330 and 540 mg.%, and the CO_2 combining power ranged from 19 to 23 mEq/L. The total serum proteins were 6.5 grams % with a serum albumin of 3.6 grams % and a serum globulin of 2.9 grams %. A serum electrophoresis was normal. On several occasions, coffee-ground-like material was aspirated after tube feedings. The hemoglobin fell to 7.5 grams %, and the peripheral blood smear showed marked microcytosis.

Intrathecal administration of Amphotericin B in a dosage of 0.5 mg. with 20 mg. of hydrocortisone was instituted every other day. The cerebrospinal fluid pressure was 400 mg. of mercury. Right-sided seizures involving the upper and lower extremity with tonic and clonic movements supervened. Decadron 16 mg. daily was given in an effort to reduce cerebrospinal fluid pressure. The BUN rose to 45 mg. % with a creatinine of 2.5 mg.%. The patient remained in deep coma and developed a marked febrile response up to 105° F. A chest x-ray showed an acute infiltration in the right midlung field and a pathologic fracture of the distal third of the left clavicle. Chloromycetin and penicillin were administered intravenously; the patient's fever lysed to hypothermic levels. There was a marked increase in seizure activity in spite of 300 mg. of Dilantin daily. With progression of the right lower lobe pneumonia and the onset of shock, the patient expired. The total dosage of Amphotericin B was approximately 700 mg. intravenously and 10 mg. intrathecally.

Discussion

Dr. Horace Zinneman*

This elderly, colored diabetic female developed signs and symptoms of an intracranial process which was clearly of some months' duration. Later in the protocol, we see that these symptoms were manifestations of a yeast infection of the central nervous system, since Cryptococcus neoformans was cultured from the cerebrospinal fluid. However, we must also consider the possibility of a disseminated cryptococcal infection. Also we must ask: is the cryptococcal infection secondary to some other disease process known to predispose the individual to a deep mycosis? Certainly Hodgkin's disease rates foremost in one's consideration as the primary disease in which Cryptococcus is a secondary invader. Lymphosarcoma, acute leukemia, tuberculosis, sarcoidosis, and certain neoplastic diseases may also coexist with cryptococcosis. More recently, pulmonary alveolar proteinosis has been implicated as one of the associated diseases.

A history of fluctuating cervical adenopathy was obtained, and a scalene node biopsy showed non-caseating epithelioid granulomata. Now this can mean many things. Classically, this is sarcoidosis. However, we still do not know what sarcoidosis is, since the same histologic picture may be present in infections with Mycobacteria and certain fungi.

Addisonian Crisis

I do not know why this patient promptly awakened after an infusion of 300 cc. of 10% dextrose. Certainly hypoglycemia was not present. One thinks immediately of an Addisonian crisis, but the patient's blood sugar and electrolyte studies do not confirm this diagnosis. Adrenal destruction and adrenal insufficiency are known to occur in the systemic deep mycoses. A recent Mayo Clinic review reported adrenal involvement in three of nine cases of disseminated cryptococcal disease.[1] These investigators also recognized that infections with Histoplasma capsulatum frequently terminated in adrenal destruction.

Physical Examination

The patient did have a temperature when she arrived at this hospital in a comatose state. She did not have papilledema. A Grade II systolic murmur was present, and it might be interesting to know whether she always had that murmur or whether we are dealing with a new murmur. In the latter instance, we might consider the presence of a fungal endocarditis due to Cryptococcus neoformans. The neurological findings suggested bilat-

Continued

eral cerebral disease with the majority of her cerebral damage on the right side.

Laboratory Studies

The hemoglobin of 11.1 grams % is a little low for a post-menopausal woman. An erythrocyte sedimentation rate of 121 mm. per hour is also excessive for cryptococcal infection alone. These findings should alert us to the possibility of an underlying disease process. Urinalysis showed significant glycosuria as well as a urinary tract infection. I would venture to guess that we might have cultured Cryptococcus neoformans from the urine, as the organism is present in the urine in about 30% of cases. A urine culture for fungi should be part of our work-up in any suspected case of cryptococcosis.

Positive Serology

Since the Reiter protein complement fixation test was non-reactive, I think the positive serology most likely represents a biologic false positive. A false positive test for syphilis occurs in malaria, infectious mononucleosis and almost routinely after smallpox vaccination. Some neoplastic diseases, such as malignant lymphoma and particularly multiple myeloma, may be associated with similar findings. This bears no relationship to the cryptococcal infection as far as I am concerned.

Lumbar Puncture

A lumbar puncture was performed and showed yeast-like organisms. This is important. A cerebrospinal fluid sugar was 100 mg. %, which is rather high when we have a cell count of 62 per cu. mm. This finding may reflect intravenous feeding or the diabetic state. It suffices to call attention to the fact that when you have a significantly elevated white cell count in the spinal fluid, the sugar is metabolized to a low level by the leukocytes. Cryptococcus neoformans is easily identified on an India ink preparation and by culture. I wonder if we could see the x-ray films at this time?

Radiologic Findings

Dr. Shih Hao Tsai*

An admission chest x-ray revealed calcification around the arch of the aorta and in the hilar areas with diffuse accentuation of lung markings bilaterally. A faint nodular density was present in the left upper lung field and interpreted as a granuloma. Skull x-rays revealed multiple radiolucent lytic defects throughout the calvarium. The skull defects were somewhat rounded in appearance, and many were of similar size. In the occipital region of the skull, there were several larger defects thought to represent confluence of smaller lytic lesions. These skull defects were most suggestive of either multiple myeloma or metastatic carcinoma. An x-ray survey of the pelvis and spine was normal.

Here is a follow-up chest x-ray taken three days prior to death. A slight pleural effusion is present at the right base together with some infiltration in the right upper lobe which could represent either active pneumonia or a pulmonary infarction. The interesting thing here is the fracture of the distal third of the left clavicle. There is a radiolucent area at the fracture site, and this most likely represents a pathological fracture.

---

*Chief of the Radiology Service, Hennepin County General Hospital.

Dr. Horace Zinneman

Thank you, Dr. Tsai. I notice the bony defects in the skull are quite striking in that they are completely free of osteoblastic reaction at the periphery. Now, how do these defects of bone fit with a cryptococcal infection? We know that bony defects do occur in about 10% of cases of cryptococcal infection. The lesions are lytic with very little periosteal reaction and represent cryptococcal osteomyelitis. Swelling is frequently present at the site, and they are clinically tender to palpation. Bone lesions can occur in almost any bone, but particularly long bones, pelvis, ribs and clavicles. I know of no report that Cryptococcus neoformans causes punched out lesions in the skull. That would be very unusual. This is another point that suggests the cryptococcal infection is secondary to another disease state. Dr. Tsai thought he might suggest either multiple myeloma or metastatic carcinoma. Sarcoidosis could present with bony defects, but these more often occur in the terminal phalanges of the hands.

The patient's course was characterized by recurrent episodes of pulmonary infiltration. We know that the portal of entry of Cryptococcus is almost uniformly the lung. The pneumonitis could be due to Cryptococcus neoformans. A bacterial etiology seems more likely, however. The yeast infection of the central nervous system must be treated with Amphotericin B.

Therapy

It is generally advisable to begin intravenous Amphotericin B therapy at about 0.25 mg. per kilogram and increase the daily dosage to about 1.0 mg. per kilogram of body weight. An initial course of intravenous therapy consists of a total dose of two to four grams. Almost uniformly, one has to give a second course of therapy. Amphotericin B is a toxic drug, and many side effects are encountered. The patients become weak and complain of muscle pain, chills, and pain at the site of infusion. Nausea and vomiting are quite often encountered but can be alleviated with chloropromazine. Thrombophlebitis can be minimized by threading an intercath up the arm to the level of the axillary vein where there is a larger volume of blood and the drug is sufficiently diluted. If we give enough Amphotericin B intravenously, we always see a rather severe anemia due to bone-marrow depression. Similarly, the renal toxicity is cumulative once a total dose of 7 to 10 grams is exceeded. Pathologically, one sees irreversible glomerular and tubular damage with renal calcification. The therapeutic aim should be to treat the patient with a total drug dosage of under 7 grams.

In view of the patient's rapid deterioration, intrathecal Amphotericin B was surely indicated. It is customary to begin with 0.1 mg. and gradually work up to 0.5 mg. in each intrathecal injection. The addition of hydrocortisone helps circumvent the majority of the adverse reactions to therapy. One should administer the drug every other day, since Amphotericin B can be detected for about 48 hours after injection into the subarachnoid space. As Cryptococci are said to be sensitive to .03 mg. per ml., we need not give massive doses. Therapeutic complications, particularly dry arachnoiditis and paraplegia, have occurred in a few instances. For this reason I would not like to give more than 0.5 mg. in a single injection intrathecally.

The Ommaya reservoir has recently been described in the literature.[2]

Continued

This device consists of an indwelling subcutaneous capsule made of silicone rubber which fits into a cranial burr hole and is connected to a ventricular catheter. Amphotericin B is diluted and injected into the capsule and pumped into the ventricle periodically. I have had no experience with this technique. Certainly the principle of having the Amphotericin B diluted as it reaches the cerebrospinal fluid is well served. Let us remember that Amphotericin B is not an aqueous solution; it is a colloidal suspension. A new drug, Hamycin, has shown promise in experimental cryptococcosis in animals. This agent is soluble in methanolic calcium chloride. It is reported to eradicate Cryptococci from mouse brain, which is truly remarkable. Very impressive blood levels are easily obtained with Hamycin as well. We may see Amphotericin B replaced with Hamycin in the near future.

Multiple Myeloma

Now I want to go over a few things which have made me think of another condition. First of all, the hemoglobin fell to 7.5 grams % with no evidence of external bleeding. The marked elevation of the sedimentation rate is of interest here. Both of these parameters suggest an underlying malignant process. A biologic false positive serology may occur in multiple myeloma. The radiolucent defects in the skull and pathologic fracture of the clavicle suggest multiple myeloma. Similarly, recurrent pneumococcal pneumonias are the hallmark of the disease. As you know, multiple myeloma is often associated with an immunologic defect characterized by a functional agammaglobulinemia. Patients frequently have a very high serum peak which resembles gammaglobulin, but is not truly gammaglobulin. It is an immunologically inactive globulin related to gammaglobulin. The normal serum electrophoresis observed in this patient is evidence against the diagnosis of multiple myeloma. However, not all cases of multiple myeloma have the typical serum pattern of a slender, sharply circumscribed homogeneous serum peak. About 20% of all myelomas have a normal serum pattern and excrete Bence Jones proteins in the urine. Approximately 50% of all myelomas have Bence Jones proteins in the urine. Initially the proteins are in the serum, but this protein is a small molecule which readily passes through the glomerular filter and is found in the urine. Bence Jones protein is nothing more than the light chain of the gammaglobulin with a molecular weight of about 30 to 35,000. Whenever there is any reasonable suspicion of multiple myeloma, I insist on an electrophoresis of the urine and the serum. I say an electrophoresis because the standard test of Bence Jones protein, namely, acidification and boiling, is not too reliable in most hands. First of all, if you have just a little turbidity in the urine, it may be overlooked upon heating. Secondly, each Bence Jones protein has its own optimal pH for maximal precipitation. If the urine is tested at pH_5, most Bence Jones protein would show at least minimal precipitation. I don't know how many laboratories adjust their pH exactly to five. In most hospitals the determination of Bence Jones proteins is not a very reliable procedure, particularly since the albumin test strip has been used for routine urinalysis.

Initially, we do not think of multiple myeloma in this case. There was no abnormal serum peak on electrophoresis and no reversed albumin-globulin ratio. However, I am assuming this case fits into the 20% of cases which have perfectly normal serum electrophoresis with Bence Jones proteinuria. Multiple myeloma is not one of the usual underlying diseases for cryptococcosis. Nonetheless, you can see that I am taken with the possibility of multiple myeloma having given her anemia, bony defects, pathologic fractures, recurrent pneumonias, and an immunologic defect which might have facilitated the development of cryptococcosis.

Clinical Diagnosis:

Disseminated cryptococcosis
Multiple myeloma

Pathology

Dr. Robert L. Strom*

I would like to congratulate the laboratory for shedding the initial light on this diagnostic problem. The spinal fluid examination was of paramount importance in this case. A low cell count with mononuclear predominance is the rule in cryptococcosis. The absence of stainable bacteria and a minimal depression of cerebrospinal fluid sugar should alert the technologist to this diagnosis. Cryptococci are easily mistaken for lymphocytes or red blood cells on a spinal fluid counting chamber. An India ink preparation reveals budding yeast five to 15 micra in diameter with clearly defined capsules.

Cryptococcus neoformans is easily cultured on Sabourauds dextrose agar at room temperature. Non-pathogenic strains of cryptococci are excluded by demonstrating growth at 37° C on blood agar. A positive urease test helps distinguish the yeast colony of Cryptococcus neoformans from Candida species.

Post-Mortem Examination

The post-mortem examination in this case revealed several interesting findings. Both of the patient's lungs weighed in excess of 500 grams. A granuloma measuring approximately 1½ cm. in diameter was present in the left upper lobe of the lung. The lesion showed central caseation and fibrosis at the periphery with a marginal infiltration of lymphocytes and occasional multinucleated giant cells. Small adjacent areas of fibronodular infiltrate were seen in a subpleural location containing similar giant cells. On closer observation, the giant cells contained no demonstrable Cryptococci on routine hematoxylin and eosin stain (Figure 1). These foci in the lung apparently represent the portal of entry of the Cryptococcus neoformans. An active pneumonitis was present in the lung at the time of death and was the cause of the terminal infectious episode. The acute exudative reaction was most consistent with a pneumococcal pneumonia of a few days' duration.

The hilar lymph nodes were markedly enlarged and caseous. Microscopically, giant cells were seen in a background of loose pink collagen. The giant cells were frequently in a perineurial location, and some of them appeared to contain intracytoplasmic inclusions. The inclusions seen were of two general types and are illustrated in Figure 2. The giant cell in the upper right quadrant contains spherical clear areas within the cytoplasm which on hematoxylin and eosin stain strongly suggested ingested yeast organisms. I was unable to verify the presence of ingested organisms with Gomori methenamine-silver, Gridley or Mayer's mucicarmine stains. The

second large giant cell in the lower left quadrant (Figure 2) contains an asteroid. Asteroids are frequently described in sarcoidosis but are known to occur in other granulomas.

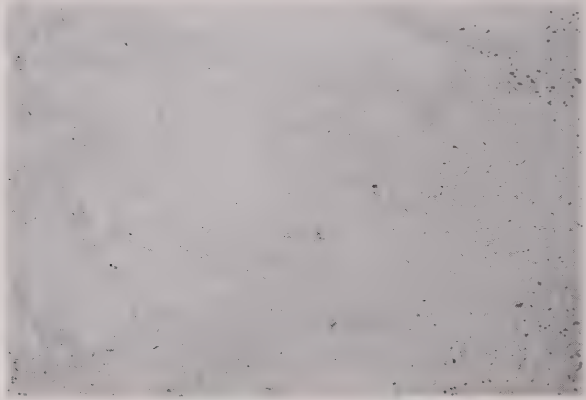

Fig. 1 — Fibronodular area from lung portal of entry showing giant cells and scarring. Hematoxylin and eosin x40.

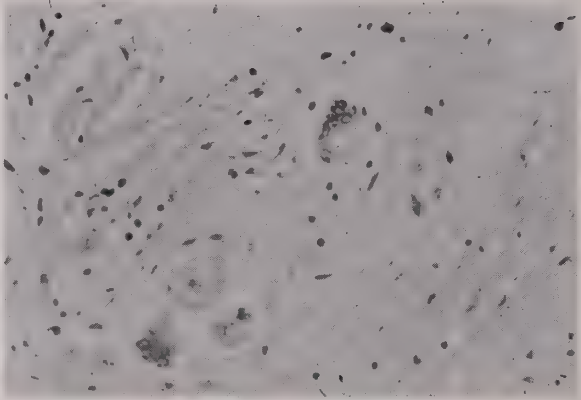

Fig. 2 — Giant cells from hilar area with intracytoplasmic inclusions. Hematoxylin and eosin x100.

At this point it is interesting to speculate about the diagnosis of noncaseating epithelioid granulomata in the cervical lymph nodes removed several months previously. Did these lymph nodes represent sarcoidosis or possibly a granulomatous reaction to Cryptococcus neoformans? Recently Harris et al.[3] have emphasized that cryptococcosis may occur in the presence of sarcoidosis. The absence of epithelioid granulomata and Schauman bodies in the hilar lymph nodes is evidence against sarcoidosis. Caseation necrosis favors progressive pulmonary cryptococcosis.

The spleen was not enlarged; it weighed 110 grams. The architecture was grossly abnormal, being replaced with granulomatous change. Intracytoplasmic inclusions were again seen in giant cells in the red pulp of the spleen (Figure 3). A solitary healed granuloma was seen in the section of liver I had available for study.

The renal tubules showed uniform necrosis with some foci of calcification in the tubular epithelium. These findings were consistent with toxic changes occurring during Amphotericin B administration. Several smaller renal arterioles were hyalinized, suggesting long-standing diabetes.

On studying the skull defects we found no evidence of multiple myeloma.

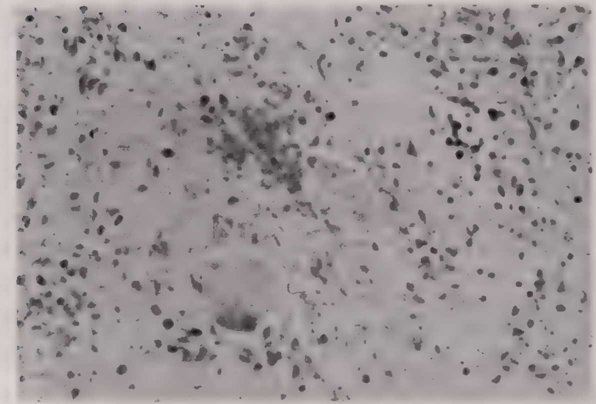

Fig. 3 — Giant cells from granuloma in spleen. Hematoxylin and eosin x100.

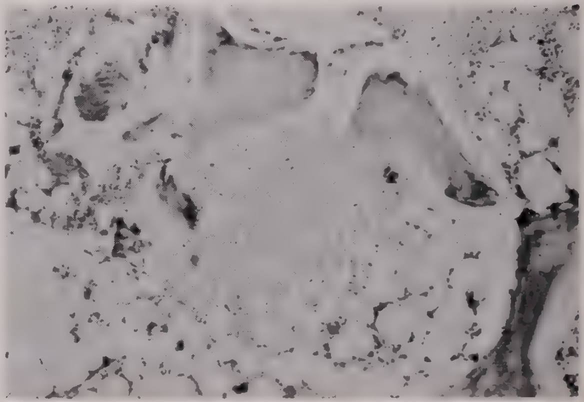

Fig. 4 — Granulomata in normal bone marrow from lytic lesions of the skull. Hematoxylin and eosin x40.

Bone marrow elements between the trabeculae showed a normal cellularity. Discrete epithelioid granulomata were seen within the marrow spaces eliciting a fibrous response and destroying adjacent bone (Figure 4). Large giant cells were present in a background of fibroblasts with a few accompanying lymphocytes and plasma cells. No stainable organisms could be demonstrated in the skull lesions. Such lytic skull lesions are unusual in either sarcoidosis or cryptococcosis.

A white cloudy exudate was present over the dorsal convexities and at the base of the brain. Coronal sections through the cerebral hemispheres revealed striking changes (Figure 5), consisting of grayish-white exudate deep within many of the sulci of all lobes of both hemispheres. Areas of softening were most voluminous in occipital sulci. The deeper cerebral structures appeared uninvolved for the most part. Although arachnoiditis and secondary hydrocephalus may occur in central nervous system cryptococcosis, there was no evidence of ventricular enlargement in this case.

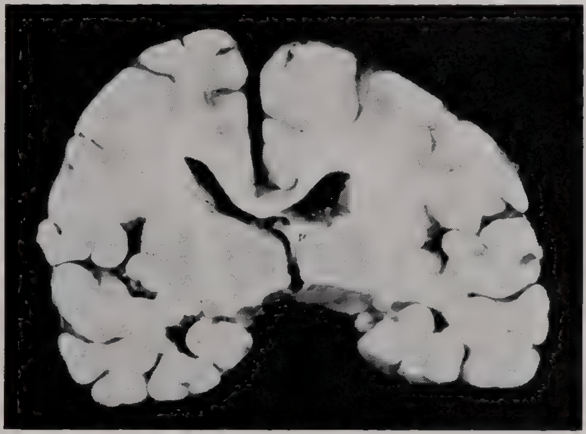

Fig. 5 — Coronal section of brain showing grayish white exudate in many cerebral sulci.

Fig. 6 — Budding organisms of Cryptococcus neoformans in brain tissue. Hematoxylin and eosin x100.

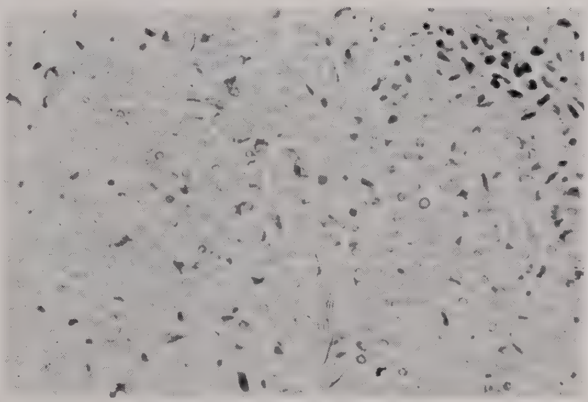

Fig. 7 — Mayer's mucicarmine stain of Cryptococcus neoformans in brain tissue. x100.

Microscopic examination of the areas of softening along the sulci showed an inflammatory process extending along the meninges and into the brain substance adjacent to cerebral vessels. Cryptococcus neoformans organisms were readily recognizable in large numbers on hematoxylin and eosin stains (Figure 6). In some areas the yeast cells were seen to bud in a characteristic fashion. When the sections were stained with Mayer's muci-

Continued

carmine technique, the organisms stood out more prominently and exhibited a reddish-pink hue (Figure 7).

We may conclude that this elderly diabetic patient has suffered a hematogenous dissemination of Cryptococcus neoformans from a primary lung focus with involvement of the brain, bones, lymph nodes and internal organs. Diabetes mellitus has been considered by some investigators to be a predisposing condition which may well have altered the patient's innate resistance. In view of the absence of stainable organisms in many of the body tissues, one may speculate on the presence of associated sarcoidosis. The lytic bone lesions particularly in the skull were indeed an unusual manifestation.

Pathological Diagnosis:

1. Disseminated cryptococcosis
2. Diabetes mellitus
3. Renal tubular necrosis due to Amphotericin B therapy

Grand Rounds

Heart Disease of Obscure Etiology in the Alcoholic*

IN A GENERAL hospital practice one not infrequently encounters a patient who has manifestations of heart disease with no readily apparent cause. It may come to attention because an incidental chest x-ray shows cardiomegaly, because a patient has an unexplained attack of pulmonary edema, because of a complaint of breathlessness on exertion or because an examination shows a well developed picture of right-sided heart failure. In an attempt to establish the etiology one reviews the common causes of heart failure. *Coronary artery disease,* being one of the more common causes, is considered but dismissed since, although the patient may have some complaints of precordial discomfort during the process of his disease or some nonspecific abnormality on his electrocardiogram, he does not have a clear-cut story of a previous myocardial infarction, a history of angina pectoris, or an electrocardiogram which shows a definite myocardial infarction pattern. *Hypertensive cardiovascular disease,* another common cause of heart failure, is not a satisfactory explanation because, although hypertension may be present during overt heart failure, the blood pressure is not elevated when the heart failure is compensated. Also the stigmata of hypertensive disease — hypertensive retinopathy, renal failure or electrocardiographic evidence for left ventricular hypertrophy — are absent. Valvular disease cannot be incriminated because of the absence of murmurs, though a systolic murmur may be present when the patient is in failure. *Cor pulmonale* is often incriminated, but the presence of unexplained left ventricular enlargement, mild clinical signs of emphysema, and the equivocal pulmonary function studies make this explanation unlikely. Occult congenital heart defects that may survive to middle adult life, such as an atrial septal defect or Eisenmenger's complex with balanced shunts, are infrequently found. One then turns to the well described uncommon causes of heart failure for an explanation.

Heart disease caused by a toxic or invasive infectious process as in bacterial endocarditis, pneumococcal pneumonia, meningococcal septicemia, diphtheria or acute rheumatic fever is usually obvious from the other

---

*Medical Grand Rounds, Hennepin County General Hospital, January 4, 1966.

Continued

clinical manifestations of the primary disease. The same may be said of the heart disease that complicates the collagen or endocrine disorders, the infiltrative cardiomyopathies and progressive neuromuscular dystrophy. When these possibilities have been exhausted and the cause of the heart disease remains unexplained, the clinician may follow one of two courses: he may call the heart disease arteriosclerotic in origin and be satisfied with rather nebulous criteria for this diagnosis, or he may call it cardiac disease of unknown origin. The former course provides some degree of ego satisfaction in assuming to know the cause, but the latter offers the excitement of an exploration into the area of cardiomyopathy of obscure etiology.[1,2,3,4,5]

I would like to discuss two forms of cardiac failure that may be seen in the alcoholic. The first, beriberi heart disease, is a well described clinical and biochemical defect which has been appreciated since 1930. The latter, cardiomyopathy of obscure etiology, is a disease which has yet to have a well developed clinical pattern described.

Beriberi Heart Disease

Beriberi heart disease represents a disorder of the cardiovascular system caused by malnutrition leading to thiamine deficiency. Two forms are currently recognized: the first is a well recognized reversible hyperkinetic circulatory state; the second is a neither well recognized nor proven irreversible hypokinetic circulatory state. The disorder arises as a result of a combination of factors which affect the circulatory system: (1) a defective energy production by the myocardial tissue, (2) a state of peripheral vasodilatation and arterial-venous shunting and (3) a disorder of vasomotor activity.

Pathophysiology

Thiamine is a 2, 5-dimethyl-6-amino pyrimidine united with 4-methyl-5-hydroxy-ethylthiazol and it is necessary for four reactions in intermediary metabolism. In the first, pyruvic acid is decarboxylated in the opening step of the reactions which feed into the citric acid cycle, and "active acetaldehyde" exists transiently on the thiamine before it is transferred to the oxidized form of lipoic acid. The second reaction occurs in a later step in the citric acid cycle. Here delta-ketoglutaric acid is decarboxylated and "active succinyl semi-aldehyde" exists in a transient fashion on the thiamine before it is transferred to lipoic acid. In the third reaction, in the direct oxidative pathway of glucose, thiamine is a coenzyme and carries "active glycoaldehyde". The fourth reaction involves alcohol metabolism. Alcohol is oxidized to acetaldehyde and then to acetic acid which enters the pathway of fat metabolism. However, the "active acetaldehyde" derived from the decarboxylation of pyruvate may use the acetaldehyde from alcohol oxidation to form acetyl methyl carbinol which is excreted in the urine. This latter mechanism is necessary when an alcohol load is imposed on the organism to prevent acetaldehyde from accumulating. However, the "active acetaldehyde" would not be available in the thiamine-deficient state.[6] Thiamine deficiency leads to a condition in which the intermediary metabolism of carbohydrate is severely deranged, and pyruvate, lactate, acetaldehyde and possibly other potentially toxic materials accumulate. Although the cardiac muscle is dependent upon carbohydrate metabolism for its energy, its derangement alone is not enough to cause symptoms of heart disease. There must be the added factor of increased venous return caused by peripheral vasodilatation. The mechanism of the vasodilatation is unknown; but it has been suggested that there is a disorder of vasomotor innervation,[7] and that elevated levels of blood pyruvate and lactate cause peripheral vasodilatation.[8]

Pathology

The pathologic lesions seen in beriberi heart disease are nonspecific and do not appear to be of an irreversible type. The major pathologic features are ventricular dilatation, usually with some increase in cardiac mass. Hydropic cellular changes and interstitial edema are the microscopic features. There is no cellular infiltration or fibrosis.[9]

Clinical Manifestations

The clinical manifestations of beriberi heart disease are variable. In the milder cases exertional dyspnea and edema are the complaints, and findings of a hyperkinetic circulation are noted — bounding pulses, systolic hypertension, tachycardia, systolic arterial sounds and a short circulation time. The illness may proceed to overt cardiac failure with narrow pulse pressure, orthopnea or pulmonary edema, cardiomegaly, pulmonary and systematic venous engorgement with elevated venous pressures. A very severe and agonizing form of cardiovascular failure may be seen, and this is termed Shoshin beriberi. Here there is a marked degree of restlessness, precordial discomfort, marked breathlessness, peripheral cyanosis and shock. This form is rapidly fatal. The overt clinical state is usually provoked by some undue exertion, increased environmental temperature or febrile disease, which leads to increased cardiac work and peripheral vasodilatation. It must also be considered as a potential complicating factor in heart disease of other etiology. Functional studies show accelerated peripheral circulation, elevated venous pressure, elevated right ventricular systolic and end systolic pressures, lowered total pulmonary resistance and lowered total peripheral resistance with edema and no cyanosis.[10,11,12] This description is that of the well recognized form of beriberi heart disease causing heart failure associated with increased cardiac output.

Alcoholic Heart Disease

In 1946 one investigator[13] suggested that the criteria for diagnosis of beriberi heart disease be broadened to include those in patients in whom no other cause for heart disease was found, who consumed a thiamine-deficient diet, who had signs of neuritis or pellagra, who had an enlarged heart with sinus rhythm, elevated venous pressure, dependent edema and recovery on treatment with decrease in the heart size. These criteria are not valid, however, since no evidence has shown that the condition results from a thiamine-deficient state, that thiamine alone will cure it, or that thiamine deficiency will lead to an irreversible form of cardiac failure. It is also a hindrance to stimulation for clinical investigation, since it would furnish a label for myocardial disease of otherwise obscure etiology, which may be due to other nutritional deficiencies or alcoholic myocardial toxicity.

An isolated form of myocardial failure is seen not infrequently in Fiedler's myocarditis, chronic myocarditis, myocardosis, idiopathic myocardial

Continued

hypertrophy, asymmetrical hypertrophy, fibroelastosis, myocarditis with endocardial elastomyofibrosis and endomyofibrosis.

Symptoms

The onset is in middle or late adult life and is insidious. The symptoms are palpitations, breathlessness and pain, as a result of embolic phenomena. The palpitations may be the result of paroxysmal rhythm disturbances, precipitated by alcohol ingestion. However, sinus tachycardia and atrial fibrillation of a constant nature may be seen in the later stages of the disease. Paroxysmal nocturnal dyspnea may occur; but this is not so prominent a feature of the disease as it is in coronary artery and hypertensive disease, since both ventricles fail simultaneously. Rather the breathlessness occurs at rest or on exertion, and orthopnea may be present. Biatrial and ventricular thrombi are a striking feature and give rise to pulmonary and systemic embolic phenomena. The history of alcoholism is frequently elicited. Since the usual intake of the alcoholic — two quarts of wine, a quart of whiskey or 15 bottles of beer daily — along with some supplemental carbohydrates, satisfies the caloric needs, the malnutrition is not readily evident by the bodily appearance.

Physical Findings

Physical examination usually shows a tachycardia, normal blood pressure and varying degrees of tachypnea. The venous pressure may be elevated and the circulation time prolonged. A previous embolus may have caused the obliteration of one of the peripheral pulses of the lower extremities. A pleural effusion may be noted due either to cardiac failure or pulmonary embolism. The heart is enlarged with an apical impulse that is down an interspace or two from normal and out near the axilla. A gallop sound is usually noted. Systolic and diastolic murmurs may be noted when failure is present and usually disappear or become less prominent when compensation is restored, a point which serves to differentiate these murmurs from those of organic valvular disease. The liver may be felt and may be tender. Ascites and edema may be present. The chest x-ray generally reveals striking cardiac enlargement, usually of all the chambers. The electrocardiogram often shows various rhythm disturbances, intraventricular condition defects, or low voltage QRS complexes. Nonspecific ST-T changes with low voltage, flat or inverted T waves, and prolonged QT interval may be present.

The pathological picture is that of a myocardial fibrosis either diffuse or focal, often perivascular with some evidence of organization and a mild inflammatory cell infiltrate.[14,15]

Treatment

The treatment is the same as for other forms of heart failure. Absolute alcohol abstinence is essential, as is a nutritious diet and prolonged bed rest, until the maximum period of compensation is achieved. Anticoagulation is used because of prolonged bed rest and also because of the tendency toward thrombus formation in the heart and veins of the lower extremities.[16,17,18] The course is frequently one of persistent and chronic congestive heart failure with generalized cardiac enlargement, despite apparent adequate treatment and abstinence from alcohol.

Case Reports

Case 1

A 42-year-old white male, a skilled laborer, was admitted to the hospital on 11/25/65 with a chief complaint of breathlessness on exertion of four weeks' duration.

He had been in his usual state of health until a month before, when he began to note breathlessness on exertion, which had progressed in severity so that he could not go up more than a few steps without becoming short of breath. Associated with the breathlessness was an epigastric burning pain which subsided with rest. He had had no orthopnea or paroxysmal nocturnal dyspnea; there had been no previous complaints suggestive of coronary artery disease or myocardial infarction; and he had no joint symptoms and no complaints suggestive of a neuritis.

He had scarlet fever at the age of 23; his father died at the age of 66 of "scar tissue on the heart"; his mother died at age 53 of cirrhosis of the liver and alcoholism; he had five siblings and four children in good health. He drank three cases of beer a week and had done so for 24 years.

Examination showed a sinus tachycardia with a rate of 100 to 110, blood pressure of 100/60 and a respiratory rate of 18. He was afebrile. The arm to tongue circulation time was 27 seconds and the venous pressure was 30 centimeters. No rales were heard in the chest. The apical impulse was prominent in the sixth intercostal space in the left anterior axillary line and a diastolic gallop was present.

Blood counts, urinalyses, serum electrolytes, blood sugars and erythrocyte sedimentation rates were normal. Mild azotemia was present, with a normal serum creatinine. There was no conclusive evidence of hepatic cirrhosis. A protein bound iodine was 8.3 micrograms per cent. Chest x-rays revealed generalized cardiac enlargement. The electrocardiogram showed a sinus tachycardia with flat T waves. One month after admission he had a pulmonary embolus to the right lower lobe. He responded slowly to therapy (digoxin, diuretics, salt restriction, and bed rest) with gradual decline in the pulse rate, but the heart size remained large.

Case 2

A white male, an unemployed, unskilled laborer, was admitted to the hospital on 10/22/63 with a complaint of chest pain and cough of a week's duration.

He had had a chronic cough, but it had become more severe during the previous week. The chest pain was pleuritic in nature and aggravated by the cough. He also complained of fatigue, lethargy and insomnia. He had no orthopnea or paroxysmal nocturnal dyspnea.

He had been seen here previously and had been in fair health except for his alcoholism. His mother and father and one sibling were in good health.

The blood pressure was 110/55, pulse 80 and regular, and respiratory rate 18. He was afebrile. The lungs were clear. The heart was enlarged to the left. The electrocardiogram showed a sinus rhythm and QT interval of 0.44 seconds. The chest x-ray showed a generalized cardiac enlargement. The blood count, urinalysis, VDRL and blood urea nitrogen were normal. Liver function studies were normal.

A diagnosis of beriberi heart disease was made. He was treated as an outpatient with thiamine, 100 milligrams twice daily, for a month.

He was admitted again on 1/22/64 with a lung abscess. The cardiovascular system was normal at that time.

His last admission was on 11/23/64 when he died suddenly in the emergency room after having a seizure. At autopsy the heart weighed 500 grams and was dilated. The microscopic pathology showed some fatty infiltration and some minimal cellular degeneration and fibrotic replacement. The lungs revealed pulmonary hemorrhage and congestion. The final cause of death was cardiac failure of undetermined cause accompanied by acute pulmonary edema.

It is interesting and perhaps of significance that between October 1963 and January 1964 this patient's congestive heart failure and cardiac enlargement completely cleared on thiamine alone without the use of digitalis, diuretics, or salt restriction. He persisted in his alcoholism and died one year later, again suffering from congestive heart failure and cardiac enlargement.

APACHE PLAZA MEDICAL COMPLEX

"Standing in the middle of a boomtown in the North . . . in the middle of a 'doctor-poor' area"—*Mayor James McNulty, St. Anthony Village, in a speech at the ground-breaking ceremony for Apache Plaza Medical Complex, November 17, 1965.*

You're right, Mayor McNulty. That's why Apache Corporation's Real Estate Division decided to build a medical complex at Apache Plaza.

We knew the statistics. While the five-county metropolitan area population was growing 13.8 per cent from 1960 to 1965, the population in the area served by Apache Plaza grew 47 per cent.

We knew the Apache Plaza area statistics on doctors, too—one g.p. for each 4,100 people, one ob-gyn for each 21,000 persons, and one pediatrician for each 17,000. And we knew that there weren't enough doctors—because our customers told us many times that the small medical facility we now have just wasn't big enough. We know another thing—the growth in this "boomtown" area, northeast of Minneapolis and northwest of St. Paul, is going to continue.

Doctors are needed. And Apache is going to offer doctors the finest medical facility in the Upper Midwest. So, Doctor, if you'd like to practice in boomtown, in a modern medical building with ample parking, pathology and radiology labs, essential ancillary services, and totally flexible space-planning, call or write:

Systemic Manifestations of Cancer

WILLIAM F. NUESSLE, M.D.
Minneapolis, Minnesota

MIGRATORY THROMBOPHLEBITIS, clubbed fingers, or the flush from carcinoid may be the first clue to the physician in his continual search for malignancy. Systemic manifestations of cancer often bear no direct relationship to primary or metastatic tumor, but rather occur at a distant site through humoral or neural influences. This secondary tumor effect may precede the visible onset of the tumor, and it may disappear following removal of the neoplasm. Study of the mechanism by which malignancy produces systemic change affords the physician a helpful means to unravel unknown facets of the cancer problem, including the cause.

Metastases to the liver, brain, or other organs frequently occur in cancer, producing dramatic effects which may dominate the clinical picture. Some of the lesser known remote effects of cancer, most of which are not related to metastases, are summarized in the Table.

Nutritional

Weight loss and cachexia have long been known as signs of cancer. Waterhouse[1] reviewed malnutrition in malignancy and indicated a triad which characterizes this host response: (1) anorexia with diminished food intake; (2) hypermetabolism for the nutritional state of the individual; and (3) wasting of body tissues. She found that the wasting affects primarily muscle and fat but probably involves all organs except the liver and brain.

Carcinoid

Carcinoid with its intriguing serotonin effect has been the basis of recent extensive medical and biochemical study. As aptly put by Moertel and coauthors,[2] almost as many papers have been written about carcinoid as there are reported cases. This neoplasm, characteristically found in the small intestine where it often metastasizes to the liver, may produce episodic flushing, watery diarrhea, and cardiopulmonary symptoms, especially bronchospasm.

Credit has been given to Lubarsch for his description of this unique small bowel tumor which he termed "little carcinoma" and to Oberndorfer who coined the term carcinoid to signify this tumor's apparent benign nature.[2,3,4] Masson[5] suggested the term "argentaffin tumor" in view of its silver-staining properties. He felt that the tumor arose from the cells of Kultschitzky in the crypts of Lieberkuhn and had a probable endocrine effect.

The location of carcinoids is usually in the gastrointestinal tract, especially the appendix and ileum. Carcinoids are the most common small intestinal tumors found at necropsy, present in 28% of a reported group.[2] They also occur in the bronchi,[6] ovaries,[7] bile ducts, and pancreas.[8]

Although first thought to be benign, carcinoid is now considered a malignant tumor.[4] In a study of 207 patients with small intestinal carcinoid, Moertel[2] found 64 with me-

Continued

tastatic lesions. Fifty-six of this group of 207 had functioning tumors. Ninety-three per cent of these carcinoids producing serotonin were found to have metastasized. Carcinoids have been found to be multiple in 29% of the cases.[2,4] Patients have had 40 and 68 primary carcinoid tumors.[4]

Carcinoid is often associated with other malignant disease.[2,4] Moertel[2] found coexistent malignant disease in 29% of his group, especially in the colon, stomach, breast, and lung. Bronchial carcinoid is more often associated with acromegaly, pluriglandular adenomatosis, and Cushing's disease than are other carcinoids.[8]

The functioning carcinoid usually produces excessive quantities of the vasopressor agent, serotonin (5-hydroxytryptamine).[9] Under ordinary circumstances only one per cent of ingested tryptophan is metabolized by way of the tryptophan-serotonin pathway. In the malignant carcinoid syndrome, 60% is so used.[10] Measurement of the serotonin metabolite 5-hydroxyindoleacetic acid (5HIAA) in the urine furnishes the most reliable guide to detection of this syndrome.[10,11]

The serotonin from carcinoid produces a wide range of symptoms.[9] Vasomotor changes include the characteristic flushing, plethora or cyanosis, and telangiectasis. The primary gastrointestinal effect is persistent diarrhea, but anorexia, nausea, and weight loss also occur. Cardiopulmonary manifestations include wheezing and bronchoconstriction as well as right and, occasionally, left[8] heart lesions. Acquired pulmonary stenosis or tricuspid regurgitation occurs[9] with thickening of the valvular endocardium.[12] Central nervous system symptoms may also be present.

The flush, which may be misinterpreted as menopausal in origin, often occurs spontaneously but may also be induced by various

procedures including histamine injection,[13] alcohol ingestion,[4] defecation,[4] enemas,[14] operative traction of the tumor,[14] and anesthesia.[15]

Treatment is primarily surgical. As much of the tumor should be removed as possible to reduce serotonin formation.[16] Surgical resection of a large liver metastasis has afforded distinct symptomatic relief.[15,17] Temporary relief can often be obtained by restricting dietary tryptophan content. Benefit by the use of serotonin antagonists including cyproheptadine (Periactin) or methysergide maleate (Sansert) and chlorpromazine (Thorazine) has been reported.[8,15,18] Antitumor chemotherapy has produced a significant decrease in liver size in one half of the trials, although there was an initial exacerbation of carcinoid symptoms.[19]

Hypoglycemia

Hypoglycemic episodes may occur in patients with pancreatic islet beta cell neoplasms termed insulinomas. Only ten per cent are malignant but these cause the more intense reactions. Multiple pancreatic lesions are found in ten per cent of the cases.[20a]

Hypoglycemia may also be associated with extrapancreatic neoplasms. Lowbeer[21] collected 48 such cases from literature. There were 25 tumors of mesodermal origin and 23 epithelial tumors. Various sarcomas were the most common tumor. There were 16 patients with primary carcinoma of the liver and five with adrenal carcinoma. Hypoglycemia has been observed in nine of 27 Chinese patients with primary carcinoma of the liver.[22] It is postulated that hypoglycemia results from production of an insulin-like substance by the tumor,[21] and such a substance has been found in bio-assay.[23]

Cushing's Syndrome*

Cushing's syndrome is often associated with tumors of the adrenal and pituitary glands but may also be present in other sources of malignancy. Riggs and Sprague[24] reviewed the findings in 232 patients with Cushing's syndrome. Seventeen (7.3%) had clinically evident pituitary tumors. The adrenal glands were explored or examined in 203 cases. Adrenal hyperplasia was present in 151, benign cortical adenoma in 27, and cortical carcinoma in 25 (12.3%) instances.

The majority of the "other malignancies" associated with Cushing's syndrome have been oat-cell carcinomas of the lung. Other neoplasias have been reported including other forms of bronchogenic carcinoma as well as malignancy of the ovary, testis, prostate, thymus, pancreas, thyroid, colon, and sympathetic chain.[25-29] Symptoms of hyperadrenocorticism may usher in the presence of pulmonary malignancy and often precede those of the tumor by several months.[25]

Two forms of hyperadrenocorticism occur. The first is typical Cushing's syndrome with the rapid onset of weight gain and peripheral edema, moon facies, an enlarged cervical fat pad, purple striae, hypertension, and diabetes mellitus. The second form does not show all the features of Cushing's syndrome but rather progressive weakness with hypokalemia, wasting, and death.[30]

In malignant disease associated with Cushing's syndrome, the adrenal glands are often found to be enlarged on pathological examination. The adrenal cortex shows hyperplasia affecting the zona fasciculata and zona reticularis but not the zona glomerulosa. Elevation of the urine excretion of 17-hydroxycorticosteroids, 17-ketogenic steroids, and 17-ketosteroids has been demonstrated.

Liddle et al.[26,28,31] have shown that the nonendocrine tumors secrete a polypeptide which is similar to pituitary adrenocorticotrophic hormone both chemically and biologically. The corticotropin-like substance has been demonstrated in the plasma and from extracts of the primary and metastatic tumor. It is assumed that the ACTH-like substance promotes growth of the adrenal cortices and that this augments secretion of corticosteroids. High levels of corticosteroids suppress the synthesis and secretion of adrenocorticotropin by the pituitary.[31]

Adrenal Insufficiency

Addison's disease may occur from metastatic carcinoma especially of the lung, while the primary lung tumor may remain virtu-

Continued

*See Minnesota Med 49:244, 1966.

ally asymptomatic.[32] In a large series of patients with lung cancer, 34% first sought medical attention because of symptoms which were due wholly or in part to metastatic lesions.[33] Forty per cent of this group of 1,070 autopsied patients had metastases to the adrenals.

Increased Antidiuretic Hormone

The presence of bronchogenic carcinoma may alter renal function to produce loss of sodium chloride. Winkler and Crankshaw[34] first described a case of lung malignancy associated with hypochloremia. Schwartz et al.[35] felt that the syndrome of renal sodium loss with hyponatremia occurred because of inappropriate secretion of antidiuretic hormone. Biological urine assay has shown increased secretion of antidiuretic substances.[36] Extracts of the lung tumor, which is often oat-cell carcinoma, have shown antidiuretic hormone-like activity.[37]

Hypercalcemia

Hypercalcemia is frequently associated with malignancy and may be the presenting manifestation. Warwick et al.[38] found hypercalcemia in 40 of 438 patients who presented for radiation therapy of their malignancy (an incidence of 9.1%). Myers[39] studied 430 patients having hypercalcemia associated with malignancy. Over one half had cancer of the breast, but lymphoma, lung, and renal neoplasias were also common. It is apparent that most instances of hypercalcemia in malignancy are associated with metastatic bone disease, though a surprising 14.3% of Myers' group[39] and 20% of Warwick's series[38] had no evident bone metastases.

Symptoms and signs of hypercalcemia include lethargy, coma, gastrointestinal and cardiorenal difficulties, including thirst, polyuria, and arrhythmia.[39] Warwick[38] found that the gastrointestinal symptoms of nausea, vomiting, anorexia, and constipation accounted for 75% of all manifestations.

Stone and co-workers[40] felt that hypercalcemia could result from metastatic bone destruction with release of calcium, but that tumor parathormone-like substance or tumor parathyroid-stimulating substance may also occur. They thought that tumor production of "substance X" which stimulated the parathyroid glands was most likely. Stone reversed hypercalcemia with surgical removal of parathyroid glands showing pathological findings consistent with secondary hyperplasia. Others feel that the tumor itself produces a biologically active parathormone substance. Serum bio-assay[41] and immunological assay of primary and metastatic tumor[42] have demonstrated such a substance. It would appear that all three mechanisms may play a role in the production of hypercalcemia.

Gynecomastia

Precocious sexual development including breast enlargement in a young girl is a well known sign of the rare thecal cell tumor of the ovary.[20c] Gynecomastia in a man may be a sign of underlying carcinoma of the lung,[43-46] hepatoma,[47] or choriocarcinoma of the testis.[20b] The gynecomastia may be the presenting complaint[43] and may disappear after the removal of the tumor.[43,47] At times the gynecomastia is associated with clubbing or hypertrophic pulmonary osteoarthropathy[43-46] or adrenal hypertrophy.[46] Increased urinary estrogens have been observed,[44-46] becoming normal after removal of the lung cancer.[46] However, Ginsberg and Brown[45] found no correlation between the presence of gynecomastia and the level of the urinary estrogens.

Pulmonary Osteoarthropathy

Remote skeletal symptoms may herald the onset of a serious visceral disease, often bronchogenic carcinoma. The skeletal manifestations may be divided into three categories—clubbing, osteoarthropathy, and arthralgia. Clubbed (Hippocratic) nails are thickened and curve over the ends of the digits which are widened distally. Osteoarthropathy (Bamberger-Marie disease) refers to periosteal thickening especially of the distal long bones. Arthralgia may be simple joint pain related to osteoarthropathy or a full-blown rheumatoid arthritis. Arthralgia often brings the patient to the doctor; clubbing is an obvious physical finding; while osteoarthropathy may be noted on physical inspection but is verified by radiographic examination.

Clubbing of the fingers is probably an early stage of secondary hypertrophic osteoarthropathy.[48] Hansen[49] believes that clubbing is more apt to occur in diffuse lung disease such as bronchiectasis. He feels that osteoarthropathy is often found in localized pulmonary lesions including cancer or abscess, with the skeletal manifestations developing and disappearing more rapidly. Clubbing, periostitis, and synovitis have been considered a classical triad in pulmonary osteoarthropathy.[50]

Hypertrophic osteoarthropathy may be an idiopathic familial disorder termed pachydermoperiostosis. This syndrome is characterized by clubbed nails, bony changes, coarse facial features, and thickened skin producing a furrowed forehead and bulldog scalp.[51,52] This idiopathic or primary osteoarthropathy cannot be distinguished from the form secondary to pulmonary disease. The presence or absence of a primary lesion and the clinical course are necessary to differentiate the two forms.[52]

Although tuberculosis has been considered an important etiological factor in the past,[48] recent reports suggest that this disease rarely produces hypertrophic osteoarthropathy.[50,53] Carcinoma of the lung is felt to be the chief cause of osteoarthropathy.[49,53-58] Hammarsten and O'Leary[53] reviewed 25 papers in the English literature and found that of 91 cases of hypertrophic osteoarthropathy, 79 were associated with pulmonary neoplasm. Wierman et al.[55] noted articular manifestations in 5.2% of 481 malignant lung lesions treated surgically. Alvarez[54] carried out resection in 47 patients with carcinoma of the lung. In 12 of the 47 the earliest manifestation of the disease was "the rheumatoid syndrome of the type of Bamberger-Marie." An unusually high incidence of osteoarthropathy is present in mesothelioma. Claggett[59] found that 16 of 24 cases of localized fibrous mesothelioma of the pleura showed articular manifestations, the latter often bringing the patient to the physician.

Studies in Germany have shown increased vascularity in clubbed fingers as evidenced by enormously dilated vessels in the nail beds using capillaroscopic technique.[50] Postmortem arteriograms of clubbed fingers using barium sulfate suspension showed that arteries and arterioles were more numerous. Their lumens were widened and the ungual processes were covered with an unusually heavy arteriolar network.[60] The increased vascularity was felt to produce an increase in the tissues of the tips of the digits especially the fibrous elastic tissue of the nail beds. Unilateral clubbing has been reported in arteriovenous fistulae producing increased blood flow in the affected extremity, with regression of the clubbing following surgical correction of the fistula.[61] Surgical removal of the related bronchogenic carcinoma often produces dramatic relief of the articular symptoms.[49,53,55,56,58] Radiographic examination several months after surgical removal of lung tumor has shown absorption of subperiosteal new bone and disappearance of osteoporosis in the long bones affected by osteoarthropathy.[56] Rheumatoid arthritis associated with carcinoma of the prostate has been symptomatically cured with estrogen therapy,[62] and that related to breast carcinoma has been alleviated with testosterone.[63]

Flavell[57] believes that only a neural reflex could explain the abrupt and consistent cessation of the pain of osteoarthropathy which follows resection of lung tumor. He performed vagotomy on five patients with inoperable bronchogenic carcinoma and hypertrophic osteoarthropathy. The neural surgery produced dramatic relief of articular pain and disappearance of joint swelling.

Gout

Gouty arthritis occasionally occurs in leukemia and other malignancy. In a series of 520 patients with gout, Kuzell et al. found that six were secondary to leukemia, Hodgkin's disease, and multiple myeloma.[64] Lynch[65] found hyperuricemia in 72 of 116 patients with leukemia, with three instances of gouty arthritis. The hyperuricemia is felt to result from increased catabolism of nucleic acid of the leukemic cells.[66]

Anemia

In an excellent analysis by Hyman[67] the

Continued

problem of anemia in malignancy was recently reviewed. Since the pathologic studies of Virchow in the late 19th century, anemia in cancer patients has been thought by many to be related to bone-marrow replacement by tumor cells. Newer studies have shown that multiple factors play a role. Blood loss from a bleeding tumor frequently produces anemia and may bring the patient to the doctor. Hemolytic factors are often important in malignancy, especially lymphoma.

Erythrocythemia

Ruddy facies, a laboratory report of elevated hemoglobin, or other signs of polycythemia may be associated with, and possibly the first sign of, renal or hepatic malignancy. Erythrocythemia is felt to be a better term than polycythemia, for in cancer, erythrocytosis is present without splenomegaly, leukocytosis, or thrombocytosis.[68-70]

In Hypernephroma

In 1958 Damon and co-workers[68] presented ten patients with erythrocytosis and renal carcinoma and reviewed 12 other reports from the literature. The ten cases represented 4.4% of 205 patients with polycythemia and 2.6% of 350 individuals with renal carcinoma. Thiel in Germany found polycythemia in 5.6% of renal malignancy at autopsy.[71] The erythrocythemia is often corrected by surgical removal of the diseased kidney.[68,69,71] Erythropoietin, usually found in the normal kidney, has been found to be increased in the plasma in these patients[71] and is felt to be the bone-marrow stimulus to red cell production.[68,71] If hematuria occurs in a patient with polycythemia, urologic investigation is essential.[68]

In Hepatoma

Working with Chinese patients in Hong Kong, McFadzean and associates[70,72] demonstrated a high incidence of erythrocythemia in 145 patients with hepatocellular carcinoma. They found 17 patients (11.7%) in this category.[70] Plasma erythropoietic stimulating factor was not increased in four patients studied. Only scattered American cases have been reported.[73-75]

Leukemoid Reactions

The finding of a leukemoid reaction in the laboratory should alert the physician to the possibility of cancer. The increase in granulocytes, especially eosinophils, usually means metastatic carcinoma and thus a poor prognosis.[69,76] Leuko-erythroblastosis refers to an increase in the circulating blood of immature leukocytes of the myeloid series and also nucleated red blood cells which may occur in cancer of the breast, prostate, lung, and other organs.[77a]

Cryoglobulins

Laboratory detection of cold-precipitable serum proteins (cryoglobulins) may be the initial finding in cryptic cancer. Cryoglobulinemia occurs most often in multiple myeloma or macroglobulinemia but may also be present in chronic lymphatic leukemia, lymphosarcoma, and other malignancy.[77b,78]

Cryofibrinogenemia has been detected in patients with neoplastic and other disease. Its presence may account for the clinical paradox of intravascular clotting appearing simultaneously with hemorrhagic diathesis.[79,80]

Hemorrhage

Hemorrhage as a sign of malignancy may occur from thrombocytopenia in leukemia, lymphoma, and other malignancy.[81] Fibrinolytic purpura occurs in prostatic and other cancer, possibly from fibrin destruction by the enzyme, fibrinolysin.[82] Hypofibrinogenemia has been a problem in patients with carcinoma of the pancreas and stomach.[81]

Hypertension

Hypertension may be an indication of excessive catecholamine hormone secretion from a pheochromocytoma. Epinephrine produces paroxysmal* and norepinephrine sustained hypertension. Approximately ten per cent of these tumors are malignant.[83]

Thrombophlebitis

Thrombophlebitis migrans or deep vein thrombosis is often seen in association with cancer, especially of the pancreas, but also of the lung, stomach, gallbladder, uterus, and ovary,[84-88,89b] and may occur as a complication of extensive malignancy. Often, however, the venous disturbance may occur before other specific signs of malignant disease and may be the harbinger of the presence of occult cancer.

---

*See Test Your Word Score Page 607.

Historical

Trousseau[90] first described a relationship between thrombophlebitis and cancer. Barker[91] found that in noninfectious systemic disease complicated by venous thrombosis and embolism, 27 of a group of 58 had malignancy. In 1938 Sproul[8 4]studied the frequency of carcinoma and thrombosis in 4,258 necropsies at Presbyterian Hospital in New York and found that in carcinoma of the body or tail of the pancreas 56.2% showed distant venous thrombosis. Thromboses were multiple in 31.3% of this group. In carcinoma of the head of the pancreas, 16.1% had thrombosis with 9.7% multiple. Of five with carcinoma of the body or tail of the pancreas who also had multiple thromboses, four showed nonbacterial vegetations on the mitral or aortic heart valves. Perlow and Daniels[86] reported ten instances of venous thrombosis in malignancy. Six of the ten cancers occurred in the pancreas and the lung. Seven of this group of ten were inoperable when the thrombosis occurred. In 1956 Wooling and Shick[87] described 15 cases of unsuspected malignant disease in which thrombophlebitis was the principal symptom which lead the patient to the doctor. Three originated in the pancreas and three in the ovary. Wright et al.[92,93] reviewed the records of 1,400 patients with the diagnosis of venous thrombosis or thrombophlebitis. Eighty-one of these had associated cancer, with 19 originating in the lung and ten in the pancreas.

Etiology

In patients with cancer, predisposing factors such as injury, surgery, pregnancy, blood dyscrasia, and varicosities may play a role in the production of thrombophlebitis.[86,87] However, it would appear that a humoral influence producing hypercoagulability often precipitates thrombosis in malignancy.[84,92,93]

Tissue destruction with release of tissue thromboplastin which would predispose to thrombosis has been considered. However, thrombophlebitis often antedates the symptoms of tumor when tissue destruction would be minimal.[94]

Sproul found that the nonbacterial valvular vegetations occurring with thrombosis in malignancy were composed of masses of fibrin and represented evidence of a hypercoagulability state.[84] Evidence of hypercoagulability was found by Amundson and coworkers[95] in 22 of 30 patients with various malignant diseases. There were elevated levels of antihemophilic globulin as measured by an accelerated thromboplastin generation test.

Manifestations

Durham indicated in 1955 that two types of thromboses occur in visceral carcinoma.[85] The first is indistinguishable from ordinary thrombophlebitis while the second is thrombophlebitis migrans. Bilateral phlegmasia cerulea dolens (massive venous thrombosis) with terminal gangrene of the feet,[86] and renal vein thrombosis producing a nephrotic syndrome[96] have been reported. Some feel that metastatic lesions usually have occurred by the time thrombosis first develops.[89b]

Persistence of an elevated sedimentation rate in a patient with thrombophlebitis should make one consider malignancy.[87] If a patient has had two or more episodes of idiopathic thrombophlebitis, a diligent search for underlying neoplasm should be made.[85-87,97] If a person with migrating thrombophlebitis shows embolic phenomena from apparent nonbacterial endocarditis, a diagnosis of visceral carcinoma can be made almost without question.[85]

Thrombophlebitis related to malignancy responds poorly to anticoagulant therapy with frequent recurrent phlebitis and pulmonary emboli.[86,87] Thrombophlebitis which is resistant to anticoagulants is often the first indication of malignant disease.[92,93] Recurrent thrombophlebitis may cease with removal of an associated malignant tumor.[87,89b,93,97]

Unilateral Lymphedema

Unilateral lymphedema of an extremity may be the initial complaint or the only finding in a patient with neoplastic disease.[98]

Continued

The malignancy may be a lymphoma or may originate in the prostate, testes, uterus, vulva, or breast.[89a,98] Lymphangiography has been advocated to differentiate primary and secondary lymphedema.[98]

Zollinger-Ellison Syndrome

Intractable peptic ulcer with production of copious amounts of gastric acid may be a sign of underlying malignant disease. In 1955 Zollinger and Ellison described this syndrome with tumor of the pancreatic islets which they felt produced a humoral factor inducing gastric hypersecretion and peptic ulcer.[99] Pancreatic tumor has been found to be malignant in one half of the cases,[100] with benign hyperplasia or adenoma in the others.

Priest and Alexander in 1957[101] called attention to the associated diarrhea which is often profound, inducing electrolytic loss and life-threatening hypokalemia.[101-103] Diarrhea has been found in 25% of patients with the Zollinger-Ellison syndrome[104] and is the only symptom in ten per cent of the cases.[105]

Pathology

Of the pancreatic tumors that are malignant one third are metastatic when first discovered.[106] The secondary tumor tissue usually found in the liver or surrounding lymph nodes often continues to function after the primary tumor is removed, so that the ulcer diathesis remains a problem. Of the benign ulcerogenic pancreatic growths 20% are aberrant,[100] while 12% are found to be simple hyperplasia.[104] The pancreatic nodules representing carcinoma or adenoma, which vary in size from 2 millimeters to 6.5 centimeters, are multiple in 10 per cent of the cases.[104]

Histopathology

Bloodworth and Elliot[107] studied pancreatic islet-cell lesions including hyperplasia, neoformation, adenoma, and carcinoma. They found the four islet-cell types: namely, alpha, beta, delta, and "non-specific" cells. Secretory granules were found in the alpha and beta cells. Proliferation of the alpha cells was found in pancreatic neoplasia associated with the ulcerogenic syndrome.

Gastrin

Gastrin is an endocrine hormone found in the gastric antrum which passes to the parietal cells of the stomach by diffusion or the blood stream to induce gastric secretion.[108] In 1960[109,110] a gastrin-like secretagogue was extracted from pancreatic islet-cell tumors in patients with the Zollinger-Ellison syndrome. The gastrin-like substance has been extracted from metastatic nonbeta islet-cell tumor[105,111] but has also been found in beta-cell insulinomas[111] and to a lesser extent in normal pancreas.[112]

Pathophysiology

It is assumed that the alpha secretory cells in the pancreatic neoplasia of patients with Zollinger-Ellison syndrome produce excess amounts of gastrin which cause gastric hypersecretion and hyperacidity. In 31 cases where 12-hour gastric aspiration was measured the volumes of gastric juice ranged from 350 milliliters to 6,900 milliliters, with an average of 2,500 milliliters.[104] The diarrhea is felt to be a direct result of gastric hypersecretion.[106] Steatorrhea and other signs of malabsorption have been reported,[113] possibly from inactivation of lipase and other pancreatic enzymes by the overwhelming acidity in the upper intestine. In a review of 86 documented cases, Christlieb and Schuster[104] found that the initial symptoms were epigastric pain in 81%, vomiting in 51%, weight loss in 36%, and diarrhea in 25%. Gastrointestinal bleeding in the form of melena (21%) and hematemesis (15%) was common. The pancreatic malignancies are slow-growing and the symptoms of peptic ulceration remain the predominant problem.[114]

Therapy

Medical management has been noncurative in the Zollinger-Ellison syndrome. Gastric resection with surgical removal of pancreatic tumors is the treatment of choice.[102,104,105,114,115] Surprisingly, a 20-month remission of peptic ulceration and diarrhea has been reported following single lymph node biopsy.[116]

See Minnesota Med 46:864, 1963.

Pluriglandular Syndrome

Hyperplasia and adenoma of other endocrine glands occur frequently in the Zollinger-Ellison syndrome.[106,114] There appears to be a relationship to multiple endocrine adenomatosis described by Underdahl et al.[117] in 1953. They reported two or three adenomas of the pituitary gland, pancreatic islets, and parathyroid gland which occurred simultaneously in eight patients, with review of 14 other cases from the literature. In 1954, Wermer[118] reported adenomatosis of the same glands in a man and four of nine siblings. He felt that this apparently inherited syndrome was caused by a dominant autosomal gene with a high degree of penetrance. Wermer called attention to the greater frequency of peptic ulcer in patients with endocrine adenomatosis.

The relationship of the inherited adenomatosis to the Zollinger-Ellison syndrome is uncertain. Pender[119] described a man with typical ulcerogenic tumor, whose daughter had had an islet-cell insulinoma removed.

Roth and Vilardell[120] studied patients with pituitary adenomas and found peptic ulcer to be common where there was polyglandular endocrine adenomatosis. In those with the latter syndrome, peptic ulcer was present in 16 of 28 patients with pancreatic adenoma and in 13 of 31 patients with parathyroid adenoma.

In the review of the Zollinger-Ellison syndrome by Christlieb and Schuster, tumors of other endocrine glands were found in 37% of cases and in 50% of those autopsied.[104] Neoplasia of the parathyroid, adrenal, and pituitary glands was common, but that of the thyroid and beta-cell pancreatic islets was rare. Carcinoid is also implicated in this syndrome. Williams and Celestin[121] reported an interesting case of bronchial carcinoid in a patient who also had multiple adenomas of the pituitary, parathyroid, pancreatic islets, and adrenal. Two of the pancreatic tumors were malignant, and there were metastases to nodes and liver.

Pheochromocytoma has been reported with pituitary adenoma. Increased growth hormone was suspected as a stimulus to the adrenal medulla.[122]

Cushman[123] reviewed familial pheochromocytoma and added two kindreds to ten others from the literature. There were 32 cases of pheochromocytoma in these 12 families. He felt that inheritance was by simple autosomal dominance. In one family, three individuals had two pheochromocytomas, two thyroid carcinomas, and one parathyroid adenoma. Cushman suggested that thyroid and adrenal medullary tumors might be added to the pluriglandular group.

It is likely that the alpha-cell pancreatic islet tumors are but one category in multiple endocrine glandular adenomas and carcinomas.

Hypokalemic Diarrhea

Villous adenocarcinoma of the colon may produce marked diarrhea with hypokalemia. Shamblin et al.[124] reviewed 21 cases of villous adenoma, of which eight (38%) were malignant and two (9.5%) had metastasized. Predominant symptoms were diarrhea, weakness, fainting, and shock.

Nervous System

The nervous system is a frequent site of systemic effect of malignancy. Symptoms of anxiety or depression out of proportion to physical complaints often occur in patients with carcinoma of the pancreas.[94,125,126] Mental changes varying from slight mental dullness to toxic psychosis may dominate the picture of lung cancer.[94] Various types of carcinoma have been associated with dementia, producing progressive intellectual impairment and memory failure.[127]

Historical

There have been scattered reports of neurological disorders in patients with cancer including carcinoma of the lung,[128,129] myeloma,[130-132] and lymphoma.[133] Brain and Henson[127] summarized their experience with 42 patients having neurological disease with malignancies, thirty-two of which occurred in the lung. They used the term "carcinomatous neuromyopathy" to describe the whole group. They considered the sensory neuropathies with posterior root ganglion degeneration and the cortical cerebellar degenerations with loss of Purkinje cells to be

Continued

the purer forms.

Etiology

The cause of the neurological syndromes seen in malignancy is unknown. Considerations have included carcinotoxins, infection, sensitization, metabolic or endocrine disorders,[127] and protein derangement.[133] Brain and Henson indicate that any explanatory theory must take cognizance of the following: (1) Only a very small proportion of patients suffering from carcinoma develop neuromyopathy (about five per cent of patients with lung carcinoma); (2) There is no relation between the size of the growth and the liability to neuromyopathy; (3) The incidence of neuromyopathy is much higher in lung cancer than in carcinoma elsewhere.

Manifestations

Cortical cerebellar degeneration produces vertigo, ataxia, dysarthria, nystagmus, and dementia.

Peripheral neuropathy may produce numbness, paresthesias, ataxia, or muscular weakness. Siemsen and Meister described a patient who presented with severe orthostatic hypotension felt to be related to neuropathy from carcinoma of the lung.[134] Guillain-Barre syndrome has been reported in patients with Hodgkin's disease and lung cancer.[135]

Neuromuscular signs include weakness of limbs and trunk, diplopia, ptosis, and bulbar paresis.[127] Myasthenia has been an occasional feature[127,129] with inconstant and, at times, temporary favorable response to neostigmine. Differential diagnosis included thyrotoxic myopathy, myasthenia gravis, dermatomyositis, and polymyositis.

Laboratory

Spinal fluid protein may be elevated with neuropathy.[127,128] A majority of the cases of corticocerebellar and encephalomyelitic syndromes showed some findings on spinal tap, including lymphocytic pleocytosis, increased protein, and paretic colloidal gold curve.[127]

Treatment

Therapy for the more serious neurological syndromes is symptomatic. Only one of Brain and Henson's group improved after surgical removal of the cancer.

Richardson[136] described an unusual demyelinating disorder of the cerebral white matter, which he termed progressive multifocal leukoencephalopathy. Seventeen of 22 cases were associated with lymphoma, leukemia, and carcinomatosis. There were signs of asymmetrical disease of the cerebral hemispheres with hemiparesis present in 17, aphasia in seven, and homonymous hemianopsia in five. An auto-immune process secondary to tumor has been suggested to produce this syndrome.[137]

Cryptococcosis is a fungus infection which often produces meningoencephalitis and is prone to occur in patients with lymphoma. In 60 well-documented cases of cryptococcosis,[138] 46 had central nervous system involvement and 18 had associated malignant disease of the reticuloendothelial system.

Meningitis can occur from carcinomatosis of the meninges, and the syndrome is often characterized by lack of fever and low glucose level in the cerebrospinal fluid.[139]

Dermatomyositis

The presence of dermatomyositis necessitates an intense search for malignancy. Curtis et al.[140] found eight malignancies in 45 patients with dermatomyositis. Williams[141] reviewed 590 cases of dermatomyositis from the literature and found 92 instances of accompanying malignancy (an incidence of 15.3%). Malignancies were especially common in the stomach, female genital organs, lungs, and reticuloendothelial system. In the Curtis series,[140] the onset of dermatomyositis preceded the appearance of tumor by an average of one and a half years. Dermatomyositis frequently improves following treatment of the associated neoplasm.[140,142]

Acanthosis Nigricans

Finding the hyperpigmented skin lesions of acanthosis nigricans in adults past 40 should initiate a search for occult malignancy. Juvenile acanthosis nigricans is not related to cancer. The pigmentation which involves the basal layers of epidermis is present in confluent verrucous lesions of the axillae, nipples, umbilicus, and genital area. Related malignancy, especially in the stomach, liver, pancreas, and lung,[143,144] is present in almost 100% of the cases.[145]

Bowen's Disease

Bowen's disease is a term applied to multiple superficial basal-cell epitheliomata, often the "forerunner" of internal malignancy.[146] Peterka and co-workers[147] found cancer in 11 of 33 patients with Bowen's disease occurring in a covered area. They also found that when Bowen's disease was present in an exposed area of the body, only one in 20 had internal cancer. Graham and Helwig[148] reviewed the relationship of Bowen's disease to systemic cancer. Of 155 cases of the disease, 75 were associated with premalignant or malignant lesions. Thirty-seven of these, or 23.9%, had primary internal cancer. Haserick[144] felt that Bowen's disease was often the result of previous arsenic ingestion and also believed that the internal malignancy could be the result of arsenic intoxication.

Carcinoma of the Skin

The presence of a skin cancer increases the probability of internal malignancy. Carpenter and co-workers evaluated statistics from a large tumor clinic registry and found 2,433 patients with skin cancer. Of these, 197, or eight per cent, were found to have another malignancy. The diagnosis of basal or squamous carcinoma necessitates further search for hidden cancer.[149]

Herpes Zoster

Herpes zoster occurs commonly in malignancy, especially lymphoma. However, evidence of the neoplastic disease has been found to antedate herpes zoster in all cases.[145] Burgoon et al.[150] found only one instance of lymphoblastoma in a series of 206 patients with herpes zoster. A greater incidence occurred at the Mayo Clinic[151] where lymphoma was present in 39 of 916 patients with herpes zoster (4.2%).

In a study of patients with blood dyscrasia, Shanbrom et al.[152] found that there were no instances of herpes zoster in 81 cases of acute leukemia. However, in 303 patients with chronic leukemia, lymphoma, or myeloma, herpes zoster developed in 24, a frequency of 7.9%. They found that treatment with radiation, alkylating agents, and corticosteroids preceded the onset of herpes in 20 of these cases.

Malignant neoplasia of the hematopoietic tissues increases the likelihood of disseminated herpes zoster. In 17 cases of disseminated herpes, such neoplasm was seen in ten (59%).[153]

Dermatitis Herpetiformis

Dermatitis herpetiformis may usher in the presence of cancer of the female organs, thyroid, or stomach. Necrotic tumors are felt to be more apt to produce the skin change. The eruption may regress during treatment of the tumor and return with recurrent malignancy.[145]

Pruritus

Generalized itching is often present in lymphoma and other malignancy.[145,154] Haserick[144] feels that pruritus does not occur in cancer except when the pancreas or liver are involved. It may precede other manifestations of cancer and is therefore a valuable premonitory sign. Pruritus will often disappear when the tumor is removed and may return with recurrent malignancy.[145]

Urticaria

Persistent generalized urticaria has been found in patients with cancer of the rectum, hydatidiform mole, and Hodgkin's disease. Toxins from the tumor are felt to act as endogenous allergens. Disappearance of the cutaneous eruption follows removal of the tumor.[145]

Erythema Multiforme

Erythema multiforme may appear one to 21 days following radiation of cancer or lymphosarcoma. It is assumed that the eruption is secondary to toxic proteins absorbed following tissue destruction. Repeated radiation may cause recurrent skin disease. Erythema multiforme may also occur without radiation at the time of discovery of an associated malignancy.[145]

Erythema Gyratum Repens

Erythema gyratum repens is a rare pru-

Continued

ritic erythematous disorder which has been described in cancer of the breast[155,156] and lung.[154] The unusual gyrate or serpiginous bands give the appearance of wooden paneling, and its borders advance slowly day by day with clearing behind. The eruption, apparently toxic, has been observed to disappear after radical mastectomy for breast carcinoma.[155,156]

Peutz-Jeghers Syndrome

Multiple polyposis of the colon which is often familial is known to be a forerunner of malignancy.[157] The Peutz-Jeghers syndrome is a rare medical curiosity with scattered mucocutaneous melanin pigmentation and gastrointestinal polyposis. Credit is given to Peutz by Jeghers[158] in his description of ten cases of this syndrome. Others were added, so that in 1957 Bartholomew's group[159] collected 75 cases including seven of their own. The Peutz-Jeghers syndrome is familial and considered a dominant inherited gene by most observers.[159-161] Approximately 40% of the patients have relatives who have both the pigmentation and polyps.[159]

Pigmentation about the mouth in an individual having abdominal pain or gastrointestinal bleeding should alert the physician to this disorder. The melanin deposits are seen on the skin of the digits, about the eyes or across the bridge of the nose, or on the mucous membranes of the lips, buccal mucosa, gingiva, or hard palate. Polypi occur in the stomach, small intestine, and colon. There is controversy whether the polypi can become malignant[162] or are simply developmental hamartomas.[159] Achord and Proctor[163] agreed that the reported 20% malignant change was debatable, but described a case with a gastric polyp and hepatic metastasis. The Peutz-Jeghers syndrome has been described in association with granulosa-theca-cell tumor of the ovary, productive of premature precocity.[164]

Anhydrosis

Anhydrosis has been shown to be the herald sign of multiple myeloma[165] and Hodgkin's disease.[166] Degeneration of the secretory cells of the sweat glands has been shown on pathological examination.

Acquired Ichthyosis

Acquired ichthyosis has been found in Hodgkin's disease, lymphosarcoma, and carcinomatosis.[145,154,166,167] Dry and cracking skin, hyperkeratotic palms and soles, and alopecia have been described. The skin has returned to normal after treatment of the cancer with x-ray and nitrogen mustard.[167] Liver damage and impairment of vitamin A metabolism are felt to induce the skin change.[145]

Hyperkeratosis

Hyperkeratosis with skin pigmentation has been found in patients with carcinoma of the lung, prostate, and breast. Application and removal of adhesive tape producing local depigmentation was recently devised as a test in these individuals.[168]

Acquired Hypertrichosis

Acquired hypertrichosis with fine lanugo hair growing on the face has been described in malignancy.[144]

Conclusions

The "mediator" of the systemic change is frequently a hormone. The pluriglandular syndrome bears an important relationship to the endocrine effect in cancer. More study is necessary to further clarify the reason why 29% of carcinoids are associated with other malignancy. Awareness of the systemic manifestations of cancer will help the clinician in earlier detection of malignancy and may give helpful information as to cause of cancer.

Random Cases of Cancer Illustrating Systemic Effect

Case 1 — Secondary Gout

The patient was a 77-year-old man who was found to have chronic lymphatic leukemia in 1960. He was treated with nitrogen mustard (mechlorethamine hydrochloride) and chlorambucil (Leukeran). General arthralgia became a problem in April of 1962. Uric acid was 7.7 mgm. %. Symptomatic relief occurred with phenylbutazone (Butazolidin). The patient was maintained on probenecid (Benemid) until his death in 1964 with little arthritic pain.

Comment: Secondary gout occurs in leukemia and other diseases of the hematopoietic system.

Case 2 — Eosinophilia

Fatigue and lassitude brought this 92-year-old male to the office in April, 1965. He gave a history of chronic bronchitis, transurethral resection of the prostate in 1949, and negative biopsy of the prostate in 1962 for a suspicious-feeling gland. Examination showed a firm prostate, moderately enlarged. The hemoglobin was 11.1 grams and the white blood count 11,350 with 41% eosinophils. Chest x-ray showed diffuse osteoblastic metastases.

The patient was referred to a charity cancer hospital where alkaline phosphatase was 180 King-Armstrong units and acid phosphatase 18 with prostatic fraction of nine units. Bone marrow showed metastatic tumor presumed to originate in the prostate. He was treated with estrogens.

Comment: Marked eosinophilia was present in this man with metastatic bone malignancy.

Case 3 — Cryoglobulinemia

This 66-year-old woman was seen during hospitalization in June, 1962. She had been bothered with a purpuric eruption and edema of her legs for two months prior to admission. There had been some indigestion. Past health had been excellent. She had had a basal-cell carcinoma removed from the left cheek in 1957. Physical examination was negative except for purpura.

In doing routine laboratory tests the laboratory technician noted a precipitate in serum left overnight in the refrigerator. Hemoglobin was 9.7 grams, white blood count 3,800, sedimentation rate 53, serum albumin 3.0 grams, and globulin 1.7 grams. Repeated tests for cryoglobulins were positive. Electrophoresis before and after cold precipitation showed that five percent of the serum proteins were cryoglobulins. An upper GI series on 7-21-62 showed an antral tumor. Gastric resection was done on 7-28-62 for lymphosarcoma of the stomach with extension to the regional lymph nodes. Surgery was followed with radiation therapy. She did well thereafter except for moderate anemia with the finding of minimal hypoplasia of the bone marrow on September 17, 1964.

Comment: Evidence of cryoglobulinemia was noted by an alert laboratory technician and subsequent studies showed lymphosarcoma of the stomach.

Case 4 — Multiple Arterial Thrombi

This 51-year-old male was admitted to the hospital October 5, 1962, because of claudication involving the left leg. Apical pulmonary infiltrate had been observed since 1943 with positive Mantoux but negative tubercular cultures. The patient smoked 40 to 60 cigarettes daily. Examination showed palpable peripheral pulses with purple mottling over the left foot. The chest x-ray showed calcified and fibroid apical infiltrate consistent with old tuberculosis with slight enlargement of the left hilus. Hemoptysis occurred. Sputum was negative for the tubercle bacillus and tumor cells. On the fourth hospital day, right hemiplegia with aphasia developed. There was progressive edema and gangrene of the left leg. The patient expired on October 31, 1962.

Autopsy showed adenocarcinoma of the left lung with metastases to the reginal lymph nodes, pleura, and liver. Old tuberculosis was present. Thrombosis of the aorta and left middle cerebral artery was evident, with left femoral and renal artery emboli.

Comment: Multiple arterial thrombi with its complications dominated the picture in this patient with lung carcinoma.

Case 5 — Widespread Thrombosis

The patient was a 79-year-old male who was admitted to the hospital on November 1, 1962, because of leg pain and edema, a sore on his right ankle which failed to heal in three months, and absent foot pulses. There was alcoholism in the past with abstinence in the previous six years. A basal-cell carcinoma was removed from his left hand in June of 1962. Gangrene of the legs developed, so that bilateral supracondylar femoral amputation was performed. Bloody diarrhea occurred, with proctoscopic examination showing beefy-red denuded mucosa. It was felt that mesenteric artery thrombosis had occurred, producing a gangrenous bowel. The patient expired November 18, 1962.

Autopsy showed general arteriosclerosis with aortic thrombosis from just below the renal arteries to the common iliac. The inferior mesenteric artery was almost completely occluded. Unsuspected carcinoma of the kidney measuring two centimeters in diameter and adenocarcinoma of the prostate were present.

Comment: Autopsy showed two malignancies not suspected before death. A basal-cell carcinoma was removed at the time of onset of symptoms. Widespread thrombosis occurred in arteriosclerotic vessels necessitating bilateral leg amputation. The basal-cell carcinoma and thrombotic tendency are likely to have a relationship with the underlying malignancy.

Case 6 — Recurrent Thrombophlebitis and Bleeding

This 61-year-old housewife was seen in consultation on April 12, 1963, because of abdominal pain and anemia of 9.5 grams. Thrombophlebitis had occurred in the right leg in December, 1962, and in the left leg in March, 1963. Examination showed a systolic heart murmur, multiple ecchymotic areas, and minimal edema of the left calf from the recent thrombophlebitis.

Gastrointestinal x-rays were negative. Platelet count was 129,000, prothrombin time 15.8 seconds, Lee-White clotting time seven minutes, and Ivy bleeding time over 20 minutes. Clot retraction was complete in two hours. Fibrinolysin test for euglobulin was negative with no lysis of the fibrin clot in two hours. Qualitative fibrinogen test was normal with beginning clot formation in nine seconds and a solid clot in 60 seconds. Prothrombin consumption

Continued

test was abnormal with a value of 16.5 and a control 31.3 seconds. Partial thromboplastin test was normal with 97.8 for patient and 70.5 for control. The tests suggested qualitative platelet deficiency. Carcinoma of the pancreas was suggested. After preparation with fresh blood, exploration was carried out on May 3, 1963, and showed a pancreatic mass and metastatic adenocarcinoma to the liver. Her condition deteriorated progressively. Gangrene of the feet occurred prior to death on June 2, 1963.

Comment: Recurrent thrombophlebitis and a hemorrhagic tendency were signs of underlying pancreatic malignancy.

Case 7 — Neuromyopathy

This 55-year-old housewife was referred for medical care on December 18, 1962, by a thoracic surgeon because of inoperable adenocarcinoma of the lung with pleural and diaphragmatic metastases. She was treated with N, N′, N″,-triethylenethiophosphoramide (Thio-Tepa) intravenously with questionable success. During this time her attitude was one of indifference. On October 14, 1963, she was admitted to the hospital after having emesis, collapse, and temporary loss of consciousness, with marked weakness of the trunk and legs. Paranoid trends and periodic mental confusion were present. Peripheral muscular atrophy and fasciculations developed. Spinal fluid showed no cells and protein of 28 mgm.%. An electroencephalogram was highly abnormal. electromyography showed no myasthenic features but needle findings and nerve conduction abnormalities consistent with polyneuropathy. Prostigmin (neostigmine) was used without benefit.

As there was increasing weakness and lack of awareness, she had difficulty holding her head up as she sat by the bedside. On February 7, 1964, she was transferred to a nursing home where she expired March 3, 1964. There was no autopsy.

Comment: The patient had a severe mixed form of carcinomatous neuromyopathy.

Case 8 — Progressive Myasthenia

In October, 1958, this 52-year-old office worker had surgical removal of the soft palate and adjacent mandible for carcinoma. Cervical lymph nodes were removed and showed metastases. She did well until April, 1959, at which time she developed nausea, blurred vision, diplopia, ptosis, and ataxia. Subjective improvement occurred with edrophonium chloride (Tensilon) intravenously. Opinion was carcinomatous myopathy of the myasthenic type. Ambenonium chloride (Mytelase) and neostigmine (Prostigmin) gave temporary relief. Increased weakness, lethargy, and coma ensued. Large doses of ambenonium chloride produced no benefit and the patient expired October 29, 1959.

Autopsy showed no evidence of metastatic tumor. The cerebrum and cerebellum showed minimal diffuse demyelinization, and the medulla showed areas of gliosis.

Comment: The patient developed severe, progressive myasthenia gravis six months after surgical removal of a carcinoma of the soft palate with no residual tumor evident at death.

Case 9 — Bowen's Disease

Left cervical adenopathy was the presenting complaint in this 66-year-old man who came for examination in May, 1964. A skin lesion removed six months before showed Bowen's disease. Cervical node biopsy showed metastatic carcinoma which was felt by the pathologist to originate in the thyroid gland. Radical neck dissection and left thyroidectomy showed more metastatic tumor but no primary lesion. There was increasing fatigue and in January, 1965, a prostatic mass became evident. As a needle biopsy showed carcinoma of the prostate, bilateral orchiectomy was done and oral estrogen therapy instituted.

Comment: A diligent search for cancer should be made when Bowen's disease is found, because one in three patients will have internal malignancy.

Case 10 — Basal Cell Carcinoma

This 75-year-old male was admitted to the hospital on April 30, 1965, because of abdominal pain and an epigastric mass. There was past history of pulmonary and laryngeal tuberculosis, Addison's disease, gastrectomy for ulcer, radiographic evidence of probable diverticulitis, and basal-cell carcinoma removed from the back in 1962. Alkaline phosphatase was elevated to 23 King-Armstrong units. Liver biopsy using the Menghini needle was negative. Removal of a suspicious back lesion showed a second basal-cell carcinoma. Surgical exploration revealed metastatic carcinoma of the liver probably originating in the colon.

Comment: Two basal-cell carcinomas preceded the finding of metastatic carcinoma in the liver felt to originate in the colon which had the radiographic appearance of diverticulitis.

Case 11 — Pruritus

This 77-year-old man was found to have pernicious anemia in 1958. He soon developed pruritus which was persistent and bothersome and thought by another physician to be related to liver and vitamin B_{12} injections. In 1961 he was referred to a dermatologist who felt he had senescent pruritus. Increasing weakness and ataxia occurred. Physical examination was negative except for a two-centimeter mass above the left clavicle. As his condition rapidly deteriorated, he could not have diagnostic studies, and he expired February 3, 1962.

Autopsy showed a malignant lymphoma of the Hodgkin's type involving the mediastinal and cervical lymph nodes, spleen, pancreas, and retroperitoneal areas. Arteriosclerosis and encephalomalacia were present.

Comment: Pruritus present for four years was erroneously considered to be an effect of liver injections or senility when it was an apparent earmark of lymphoma.

Case 12 — Pruritus

This patient, who was a 42-year-old housewife, expired October 11, 1964, from longstanding Hodgkin's disease. She was referred in November, 1959, because of general itching and burning of the skin. In 1939 a neck node biopsy showed Hodgkin's disease. In the next 20 years she was treated only with x-ray therapy directed to evident lymph node enlargement. Fifteen courses of radiation were given to the neck, mediastinum, abdomen including pelvis, and inguinal nodes. Nitrogen mustard helped the pruritus. Herpes zoster occurred in September, 1961. Liver involvement became evident in February, 1962, with alkaline phosphatase of 111 King-Armstrong units and bromsulphalein retention of 27%. Various types of chemotherapy were used with little success. Anemia became an increasing problem and was treated with iron and corticosteroids. Back pain occurred and an x-ray in January, 1964, showed sclerosis of the lumbar vertebra consistent with Hodgkin's disease. In March, 1964, weakness of the limbs increased so that it was difficult for the patient to stand or walk. Electromyography showed scattered neuropathic polyphasic units in the right arm and both legs consistent with peripheral neuritis. A gastric ulcer occurred in June of 1964. In the six months prior to death moderate hypertension developed. Increasing cachexia and ascites occurred before death.

Autopsy showed Hodgkin's disease in the only remaining enlarged lymph node found in the femoral region. The liver showed Reed-Sternberg cells. Hemosiderosis was present in the liver and spleen. Contracted kidneys showed microscopic findings consistent with radiation nephritis. Aspiration pneumonia was the terminal event.

Comment: The patient was first seen with pruritus when her Hodgkin's disease of 20 years duration became generalized, possibly from liver involvement. Aside from pruritus, other systemic signs of malignancy included herpes zoster, anemia, peripheral neuritis, hypertension presumably from radiation nephritis, and cachexia.

The duty of the physician is to cool what is hot, to warm what is cold, to dry what is moist, and to moisten what is dry. He should look upon the patient as a besieged city, and try to rescue him with every means that art and science places at his command. The physician should be an inventor, and think out new ways and means by which the cure of the patient's affection and the relief of his symptoms may be brought about.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

HEMANGIOMA OF THE STOMACH

A Cause of Ulcer and of Gastric Hemorrhage

According to the literature, hemangioma of the stomach is so rare that only a few cases are on record. It is said to be more uncommon than in other parts of the gastrointestinal tract. The authors intend to shake the assumption that the condition is so rare and, if possible, throw some light on the mystery of the numerous cases of gastric hemorrhage of obscure cause which constitute perhaps up to 20% of all gastric hemorrhages. The very few gastric hemangiomas on record seem to have been true tumors, true new growths, either diffusely infiltrating or limited, frequently polypous, cavernous hemangiomas protruding above the level of the surrounding area and therefore usually demonstrable by x-ray.

The authors speak of changes in the gastric wall as cavernous phlebectasia but prefer the term hemangioma. "The vascular changes present themselves as small patches, 3 to 5 mm. in the mucosa, of a reddish-blue color, on or very slightly above the mucosal level." Histologically, they consist of densely placed, large, blood-filled vascular lumina, predominantly venous.

Case Reports

Case 1

A woman aged 46, previously in good health, had five episodes of gastric hemorrhage and melena, preceded by mild pressure pain in the epigastrium. It had been impossible to demonstrate the cause of bleeding. Radiography showed no abnormalities. Laboratory revealed only anemia. Gastroscopy showed an injected gastric mucosa. Close to the angular notch on the anterior aspect of the stomach there was "a small, slightly prominent area the size of half a pea which grossly suggested a hemangioma." There was also a second, smaller, similar area more proximally located. One month later the larger area under the gastroscope presented the appearance of a superficial ulcer with injected, slightly raised edges. Radiology again gave no conclusive result. A Bilroth I operation was performed, and a small ulcer was found at the site demonstrated through the gastroscope. The histological diagnosis was gastric ulcer, hemangioma of the gastric wall. During surgery several hemangiomas of sizes up to a walnut were found in the liver.

Case 2

A man aged 54 with four episodes of melena and severe anemia over six years had negative x-rays. A laparotomy with gastrostomy was negative. Two small typical hemangiomas were found in the small intestine. One year later he had another attack of melena and severe anemia. Gastroscopy revealed three or four hemangiomas on the anterior wall of the stomach. One, raised and cone shaped, had a small lump of

Continued

fibrin on top. X-ray showed an irregular mucosal pattern. A Bilroth I resection was done. At the suspected site three collapsed areas suggesting hemangiomas up to pea size without ulcer formation were found. Histological report: Fairly widespread hemangiomatous lesions in the submucosa.

Case 3

A male aged 46 had a six-year history of dyspeptic complaints. Examination was essentially negative. One year later he gave a history of profuse hematemesis and anemia, and eight months later he again had hematemesis in Holland. He was transferred to the authors in Finland. X-ray examination revealed a polypous lesion, possibly a hemangioma. Gastroscopy revealed three to four dark red, slightly elevated areas, the largest 1 cm. in diameter. A Bilroth I resection was performed. The specimen showed three small red, slightly retracted areas. Histological examination: "Stomach with angiomatous areas in the submucosa, mucosal bleeding, erosion, and scar."

Case 4

A male had a history of 10 years dyspepsia. X-ray showed a duodenal ulcer. About two years later, after more bleeding, x-ray was repeated and again reported to show a duodenal ulcer. No gastroscopy was done, but a Bilroth II operation was performed. There was scarring in the pyloric region but no recent ulcer to account for his bleeding. In the proximal stomach, reddish areas suggesting hemangiomas were found at surgery. A Bilroth II operation was again performed, disclosing hemangiomas on the liver as well as on the patient's forehead. The histologist's report indicated scarring of the duodenum. The hemangioma-like area of the stomach showed densely arranged vessels which in places occupied the entire space between the mucosa and the muscularis, where the mucosa was thin. One area showed bleeding in the mucosa at the margin of the vascular area.

Cases 5, 6, and 7 were not operated upon, but in Case 5 gastroscopy revealed four small hemangioma-like areas. He had been admitted three times for melena.

Case 6 also showed on gastroscopic examination a dark red, hemangioma-like area. He had had occasional hematemesis, melena, and anemia.

Case 7, a female of 59 years, with 20 years of gastric complaints, entered the hospital with profuse hematemesis, melena, and anemia. X-ray and laboratory examinations were essentially negative. Gastroscopy revealed two hemangioma-like areas.

In two years the authors found or diagnosed hemangiomas (cavernous phlebectasias) in seven patients, six of whom were diagnosed by gastroscopy. Four underwent surgery, and hemangiomas were found at the site observed at gastroscopy and were confirmed by histology. Unlike ordinary ulcer hemorrhages, bleeding stopped each time without emergency surgery. This, the authors state, accords with venous bleeding and also with the fact that relief has occurred following gastric resection, when no cause for bleeding was found, in so called "blind cases." Several authors have tried to find a relation between hemangiomas in the skin and in the intestinal tract. Berlyne and Berlyne are quoted as saying that in gastrointestinal bleeding of obscure causes, cavernous hemangiomas in the skin suggest that similar lesions may be present in the bowel and be responsible for the blood loss. Two of their seven patients had hemangiomas of the skin.

Gins et al. presented results of a study of surgically removed stomachs before the clinical congress of the American College of Surgeons in 1963. They could identify three types of vascular alterations: "nests of vessels" in a tangled network of thick-walled vessels in the scar tissue beneath the ulcer, found in gastric as well as duodenal ulcers to which they are not secondary, as frequently assumed. The ulcer may be related to the changed vessels of the stomach or duodenal wall. Possibly we are faced with a so-far unheeded cause of ulcerogenesis in the stomach. Findings indicate these vascular changes in the stomach partially explain the frequency of severe gastric hemorrhages of obscure cause.

None of the operated patients in their series has had gastric hemorrhage since surgery.

Comment: This report is unusual and interesting. The diagnoses via the gastroscope, when x-ray and laboratory studies were unrevealing, is unusual. Although the results are significant, this series is too small to establish positive conclusions. The authors are to be complimented on this presentation.

CHILDHOOD LOSS OF A PARENT

In 1954, 11,379 Minnesota school children were evaluated by means of the Minnesota Multiphasic Personality Inventory, and in 1957 a follow-up survey was made. Starke R. Hathaway and Elio Monachesi reported on preliminary results in *Adolescent Personality and Behavior,* published by the University of Minnesota Press in 1963. Re-evaluation of the data in terms of the relation between delinquency and socioeconomic status, family stability, and intelligence has now been summarized by Dr. Gregory. Analysis showed that delinquency was more frequent in children who had lost a parent of the same sex, whether by death, divorce, or separation, and that delinquent acts were more common in children from the lowest socioeconomic strata. However, farm children, who committed fewer delinquent acts than city children of comparable economic status, were exceptions to the latter finding. It was also noted that children from the lowest socioeconomic strata who were also of low intelligence dropped out of school more frequently than the average for the general population and that children who had lost a parent of the same sex were also more likely to leave school prematurely, regardless of their intelligence or economic circumstances. Thus, one of the important findings of this study was that the parent of the same sex as the child was crucial in the child's social development, especially in the prevention of delinquency and academic failure. The reasons for this parent's importance are probably manifold, but current thinking suggests that the most crucial one is that he provides the model on which the child bases his identity and aspirations.

SPONTANEOUS PNEUMOTHORAX

Two hundred consecutive cases of benign, nontraumatic, nontuberculous spontaneous pneumothorax, unassociated with other pulmonary diseases such as pneumonia or tumor are presented. Nearly all were men, and 80% were under 40 years of age. Right and left sides were affected equally. The median time for re-expansion of the collapsed lung was 4 weeks in the nonsurgical group, 3 weeks in the repeated needle aspiration group, and 2 weeks in a small group treated with intrapleural catheter.

SHELLAC BEZOAR OF THE STOMACH ASSOCIATED WITH OBSTRUCTION OF THE SMALL INTESTINE

Bezoar is a term applied to concretions of various foreign or intrinsic substances found in the stomach and intestine of both men and animals. They are classified as:

1. Trichobezoar — composed almost entirely of ingested hair.
2. Phytobezoar — composed largely of vegetable matter.
3. Concretions — rare types, occurring in people who ingest furniture polish, resins, paraffin, asphalt, bismuth, gums, etc.

DeBakey and Ochsner, through an exhaustive search of the world literature, collected 303 cases of bezoars and added eight of their own. The reported cases were 172 in #1, 126 in #2, and 13 in #3. Of the 13 cases in #3, eight were composed of shellac. Shellac bezoars are very rare. Added are a few more reported in Norway, Germany, Russia, and Australia.

Case Report:

A 36-year-old worker, a drunkard accustomed to alcohol in any form, started drinking various kinds of alcoholic solutions of shellac four years ago. He usually precipitated and removed most of the shellac by adding table salt before drinking the liquid portion. This was while he was in prison, where there was no alcohol available. On discharge he again drank ethyl alcohol for one week and then an average of half a liter per day of alcoholic solution of shellac for two weeks.

He then began to have stomach ache and a sensation of a large mass in his stomach. He developed a sudden attack of pain followed by nausea and vomiting and was admitted to the hospital, acutely ill with marked abdominal distension and active peristalic sounds. Gaseous distension of the small bowel suggested obstruction.

On operation a foreign body impacted in the mid-ileum was removed, consisting of a large, ovoid, brownish, coarsely-spongy structure 7 cm. at its greatest diameter. A second mass, 40 cm. long, forming a true cast of the stomach and weighing 900 gm., was removed. The specimens at first were soft but hardened rapidly and showed fissuring of their surfaces. The surface was bright yellow and glossy, but the center was black and spongy. Both concretions consisted of shellac. The smaller body removed from the ileum was a fragment from the larger mass. There were no changes in the gastric wall. The patient made an uneventful recovery.

It is noted that when the alcohol is absorbed, the shellac, which is not soluble in gastric secretions, is precipitated out and forms the bezoar. Important factors are the craving for alcohol and the fact that in most instances the subjects have worked in trades in which alcoholic solutions of shellac are used in considerable amounts.

FECALITHS OF THE APPENDIX

The records of 100 patients with appendicitis and 100 with uninflamed appendix were studied and compared as to the incidence of fecaliths. In the first group there were 17 fecaliths, of which 12 had been seen by roentgenographic examination. There were four fecaliths in the uninflamed-appendix series, and one of them had been detected radiologically. This difference of incidence in the two series suggests that fecaliths are associated with acute appendicitis about 10 to 12 times as often as with uninflamed appendices, and that the discovery of a radiopaque fecalith indicates at least a 90% chance of the presence of acute appendicitis. The characteristic roentgenographic finding is the presence of one or more laminated densities, 5 to 20 mm. in diameter, usually located within 15 cm. radius of the mid-point of the right iliac crest. Most of these densities are oval, but other shapes are often observed. The lamination may be poorly visualized, especially when the fecalith is superimposed on bone. It is recommended that immediate surgery should be performed when a fecalith is accidentally found in patients with asymptomatic appendix, especially among children. The presence of a fecalith increases the probability of complication by gangrene and perforation, as happened in 12 cases of the acute appendicitis series in this study. Given the diagnostic specificity of the fecalith sign, routine abdominal roentgenography is advisable whenever appendicitis is suspected.

REMOVAL OF OVARIES WITH HYSTERECTOMY

There are a number of sequellae that may occur as a result of estrogen deficiency: e.g., negative nitrogen balance, hypocholesterinemia with an increase in coronary atherosclerosis, hypertension, osteoporosis, atrophy of the vaginal wall, senile vaginitis and its concomitant symptoms, and urinary incontinence as a result of atrophy of the muscles and connective tissues supporting the bladder.

Despite this, Fugo points out the possibility of developing carcinoma in the remaining ovaries after hysterectomy, and he recommends salpingo-oophorectomy in all cases where hysterectomy is indicated. He further recommends that estrogen therapy be administered in all of these women, even until old age, in order to prevent metabolic and atrophic changes which are characteristic of a lack of estrogen. He states that the danger of prolonged estrogen administration is minimal.

SLEEP PARALYSIS

The literature suggests that sleep paralysis is an unusual phenomenon that occurs chiefly in narcoleptics and cataleptics. The author, however, gained the impression that it is by no means rare; that it is not usually associated with narcolepsy or catalepsy; that people do not usually consult doctors about it; and that many regard it as a personal idiosyncrasy best kept to themselves. The author investigated the incidence of sleep paralysis among 52 freshman medical students who could be regarded as generally healthy. He found that 8 (or 15.4%) responding to a questionnaire had experienced sleep paralysis. He compares his findings with those of a study by Gorde on 359 subjects, of both sexes (mostly medical and nursing students). This study had disclosed an incidence of 4.7%,

Continued

and also that the condition was 4 times more frequent in males than in females. None of those with sleep paralysis were found to be narcoleptic or cataleptic. The author likewise found no association between sleep paralysis and narcolepsy or catalepsy. Although the majority of those with sleep paralysis experience anxiety during the attacks, the remaining patients tend to feel a definitely pleasant sensation. A variety of other interesting subjective experiences may accompany sleep paralysis, some of which might be termed "depersonalization."

SPERMATOCELE

Spermatoceles are single, multilocular or multiple retention cysts of ductuli efferentes which may grow large enough to require surgical removal. Between dense fibroelastic membrane of the spermatocele sac and the cremaster, a nearly avascular cleavage plane has regularly been observed, the use of which permits separation of the lesion from surrounding tissue with minimal bleeding, trauma, or postoperative reaction. Complete removal of multiple or multilocular cystic elements favors nonrecurrence. Reconstruction of the cremaster restores normal activity of this muscle.

Medicine

Looking out on the present state and prospect of medicine, it is obvious that its future work will be mainly to prevent and stop the beginning of disease — to take good order that it shall not come, and if it do come, to prevent functional disorder from lapsing into fixed disease, which must be given over either to the surgeon's knife or to the shears of Atropos;* for to despise the little things of functional disorder is to fall by little and little into organic disease. . . . If mankind is to be perfected, the means of perfecting it must be sought in the medical sciences.

— Dr. Maudsley, President of the Section of Medicine,
to the British Medical Association, 1905.

Recent advances in communications have been spectacular. Yet there's still a lot to be said for the wink. — Changing Times

Book Reviews

A good book is the very essence of a good man. — His virtues survive in it, while the foibles and faults of his actual life are forgotten. — All the goodly company of the excellent and great sit around my table, or look down on me from yonder shelves, waiting patiently to answer my questions and enrich me with their wisdom. A precious book is a foretaste of immortality. — T. L. Cuyler

DEPRESSIVE STATES: A PHARMACOTHERAPEUTIC STUDY — by Anthony Hordern, M.D., Charles C Thomas Publishers, Springfield, Ill., 1965. 166 pages.

Dr. Hordern, at present a consultant psychiatrist at the Kings College Hospital of London, has written a scholarly review of depression and, in addition, has provided a well-designed study of an antidepressant drug. He begins his book with a discussion of the depressive syndromes, which includes a critical review of the epidemiology, phenomenology, social consequences, and complications of depression. He points out the ubiquity of depressive illness in all areas of medical practice, and he gives a careful and well-documented review of the physical therapies of depression, including electroshock, prefrontal lobotomy, and antidepressant drugs.

The greater part of the book comprises a detailed discussion of a controlled investigation of imipramine and amitriptyline. The procedures, methods, and means of statistical analysis are well described and contribute a more-than-adequate model for controlled evaluations of antidepressant agents. The statistical analyses of drug efficacy, of symptom constellations, of interaction between symptoms, and of factors like age are especially noteworthy.

Generally, the book is well-written and lucid. However, the author does include the bibliographic names in the text of the book, which makes for slow and difficult reading. The drug study described is worth careful examination by anyone interested in psychopharmacologic research, and the conclusions are certainly of value to all clinicians who treat depressed patients. Dr. Hordern's statements about the relative efficacy of amitriptyline cannot be questioned on the basis of his data, but it is possible that other therapies may be better than he implies. Also, since he did not include a placebo group in his investigation, his generalizations about the effectiveness of antidepressant drugs are open to criticism. While it is true that previous investigations suggest the superiority of both imipramine and amitriptyline over placebo, it is also true that one is more confident of statements about a drug's effectiveness in any study when a placebo control is included. Perhaps this is a small point, and it is surely one which many experienced investigators would dispute, but medical history strongly supports cautious skepticism for all therapies whose value has not been proven by time and by many controlled investigations.

In conclusion, Dr. Hordern's book will be primarily valuable to psychiatrists and clinical investigators, although it possesses sufficient clinical material to be of interest to any clinician who treats depressive illnesses. The author's review of physical therapies in depression is well done and could serve as a primer for those who are unfamiliar with the literature on these therapies.

FROM AUSCULTATION TO PHONOCARDIOGRAPHY — Aldo A. Luisada, C. V. Mosby Co., St. Louis, Missouri; 1965, 314 pages; price $17.75.

Luisada has long been known as one of the leaders in the field of heart sounds and their graphic representation. This work is a thorough study of phonocardiographic technique and its value as an adjunct and corrective to auscultation. For the clinical cardiologist and for all physicians who examine hearts there is much to learn from this volume.

Luisada divided the precordium into overlapping areas of auscultation: right atrial, right ventricular, aortic, and pulmonic areas. However, there are better landmarks that can be used to designate where a sound is heard. Luisada places one of the most important sounds in cardiac auscultation, the mitral diastolic rumble, in the area between the apex and the (left) sternal border. This murmur, however, is usually best heard exactly at the apex or slightly lateral to it and often only in that region.

The greatest value of the phonocardiogram, as Luisada repeatedly emphasizes, is its precise timing of audible events in the heart cycle. Clinicians can learn much about auscultation from phonocardiography. The phonocardiogram can often be helpful to the clinician in diagnosis.

The Minnesota Breast Cancer Clinics

CARCINOMA OF THE breast continues to be the most common fatal neoplasm of women. For most patients with this disease it is not until after the appearance of symptoms that the diagnosis is made and, more often than not, by this time the tumor is no longer localized to the breast and already presents overt evidence of spread to lymph nodes or other areas.[1] Although improved surgical techniques, chemotherapy, and radiation treatment have brightened the outlook for most cancer patients during the past 25 years, survival rates for patients with neoplasms of the breast continue to be disappointing. Presently more than half of the women found to have breast cancers can anticipate eventual death from the disease, and the outlook for 10-year survival is probably less than 40%.[2]

Improving the prognosis for breast cancer patients has been of continuing interest to physicians. The conventional treatment for this disease has been surgical, and for the past 70 years or so the conventional operation has been the so-called Halsted mastectomy. Recently, with the hopeful anticipation of achieving more complete extirpation of a greater proportion of nonlocalized breast cancers, several more extensive operative procedures have been described and, over the years, a number have undergone clinical evaluation. None of the more radical operations, unfortunately, has demonstrated a superiority in long-term survivals; in consequence, none has found wide application or acceptance. In other quarters the limited operation of simple mastectomy, accompanied by radiation therapy, has been advised. Somewhat surprisingly, recently reported survival rates following these more limited operations have differed very little from those reported for the Halsted procedure. Final evaluation of the results of the more restricted operations, however, will probably require several years.

Stimulated by the encouraging results of the widespread use of the Papanicolaou smear, increasing emphasis has been placed on the early detection of cancer. Studies of patients with breast cancers seen at the University of Minnesota Cancer Detection Center, for example, have shown that when the cancers were detected by the physician during routine annual examination, rather than

TABLE 1

Continued

found by the patient herself, the majority have had no evidence of spread beyond the breast at the time of therapy; that more than 90% of the patients with breast cancers found at the Center have been five-year survivors; and that survival at both five and 10 years has been 100% of that statistically anticipated for similar patients without breast cancer.[3]

Breast Clinics

To emphasize the importance of early detection of breast cancer, the Minnesota Division of the American Cancer Society, the Cancer Committee of the Minnesota State Medical Association, Minnesota Department of Health, and the Cancer Detection Center at the University formulated a program of breast clinics to be conducted in conjunction with professional and lay education programs. Since 1961 five such clinics have been held throughout the state.

Sponsoring Organizations

Organization and operation of the breast cancer clinics have emphasized participation at the local level. The sponsoring organizations usually have been the county medical societies, with the assistance and cooperation of members of the district units of the American Cancer Society. Local volunteers, with the coordinating help of the Minnesota Division of the Cancer Society, have been responsible for the multitude of details of arrangements and scheduling required for the successful operation of such clinics.

Education Seminar

Preceding each clinic a cancer education seminar was held for physicians of the area. The programs were presented by a faculty of University of Minnesota staff members and clinical affiliates. Methods and results of early cancer detection, lectures concerning diagnosis and treatment of neoplasms of the breast, uterus, bowel, prostate gland, lung, and other organs, and demonstrations of the techniques of breast examination comprised the seminars.

The examination clinics, usually conducted the following day, were staffed primarily by the physicians of the area. Members of the University staff, including participants in the seminar, were available for consultation and assistance. The women who underwent the breast examinations were residents of the local areas, 35 years of age or older. Participation was on the basis of interest, and no effort was made to limit the group to asymptomatic persons. Women were requested to preregister with the local unit of the American Cancer Society. An additional small number of other women were also accepted for examination after registering at the time of the clinic.

Referral to Attending Physician

The examinations at the clinics were comprised of routine methods of physical diagnosis. Mammography and other x-ray examinations were not undertaken. No treatment was performed. Breast abnormalities which were found and questionable conditions for which re-examination appeared to be indicated were reported to the private physicians designated by the patients. Those found to have abnormalities of the breast were urged to consult their own physician for further examination or evaluation. The follow-up information in this report was ob-

tained from the private physicians four months to one year after each clinic.

Results

The five breast cancer clinics held in Minnesota since 1961 were conducted in Crookston, Fergus Falls, Owatonna, Virginia-Hibbing, and Cambridge (Table 1). The age distribution of the patients examined is shown in Table 2. Based on U. S. Public Health Service estimates,[4] 7.8 breast cancers could be expected among 5,438 women of this age distribution.

Incidence of Abnormality

Of the 5,438 women examined, 375 (or

6.9%) were found by the examining physicians to have breast abnormalities or "suspicious" findings requiring referral to private physicians. Three hundred and ten (83%) of these 375 with abnormalities found at the clinics returned to their physicians for re-evaluation (Table 3). Re-evaluation by their private physicians revealed a definite breast abnormality in 57.6% of the 310 women who returned for examination.

Most Common Abnormality

The most common abnormality found was fibrocystic disease, which accounted for 77.5% of the breast abnormalities present on re-examination (Table 4). Eight cancers of the breast were found (7.8 were expected on the basis of age-specific incidence rates).

TABLE 5

Minnesota Breast Examination Clinics
1961-1965
of Each 1,000 Women Examined at the Clinics

Breast abnormality found at the clinic	69
Returned to private physician for examination	57
Breast abnormality "confirmed" by private physician	33
Fibrocystic disease found by private physician	25
No breast abnormality found by private physician	24
Adenocarcinoma	1.5
Biopsies performed	14

TABLE 6

Minnesota Breast Examination Clinics
1961-1965
Patients Who Returned to Private
Physicians for Examination*
of Each 100 Women with
Abnormalities Who Returned

Abnormality found on re-examination	57.6
Fibrocystic disease	44.4
Lipoma	3.2
Adenoma or fibroadenoma	2.9
Adenocarcinoma	2.6
Other benign breast conditions	2.5
Refused recommended biopsy	1.0
Failed re-check examination	1.0
No abnormality found on re-examination	42.4

*5.7% of all women examined in the clinics; or 83% of all women with abnormalities found in the clinics.

Three patients were found to have an abnormality for which biopsy was recommended but was refused. Another three women were requested by their physicians to return for follow-up examination but failed to do so.

Thus, of each thousand patients examined in the clinics, 69 were found to have breast abnormalities, and 57 of these returned to their private physicians for re-examination (Table 5). In 33 of each 57 (58%) who returned for re-evaluation, a breast abnormality was "confirmed." In 25, fibrocystic disease was diagnosed on re-examination, and in 24, re-examination showed only normal breast. Or, of each 100 patients examined by the private physicians for breast abnormalities as a result of the clinics, 44.4 had lesions which were diagnosed as fibrocystic disease; in 42.4 no abnormality was found; 3.2 had lipomas; 2.9 had fibromas or fibroadenomas; 2.6 were found to have cancers; 1.0 refused recommended biopsy; 1.0 failed recommended follow-up examination; and 2.5 had other benign breast conditions (Table 6).

Discussion

Although carcinoma of the breast is a relatively frequent cause of death in this country, accounting for three of each 100 deaths which occur in the female and for nearly 20% of cancer deaths in women, at any given time the prevalence rate of previously undetected breast neoplasms is substantially lower. In fact, the eight women with cancers found in the clinics included two with previously recognized lesions: one of the women had already consulted her own physician and was aware of the probable diagnosis; and the other had refused therapy for an advanced, ulcerating lesion. Two additional cancers not suspected in the clinic were detected as a direct result of referral of patients to their private physicians for further evaluation, i.e., one of the cervix and the other of the contralateral breast; both of these patients had lesions which were detected early, the prognosis for which should be excellent.

Thus the merit of regular periodic breast examinations is emphasized; and, although only a modest number of detectable but previously undiagnosed breast cancers appear to exist at any one time, these lesions seem to occur at a relatively constant rate in the population; so that at the present rate of occurrence at least one of each 20 women can be anticipated eventually to develop this disease. While the actual number of breast cancers detected was small, the acquainting of several thousand women with the ease and simplicity of breast examinations, the re-enforcement of the concept of the merit as well as the acceptability of routine examinations of asymptomatic persons, and the making known to physicians and lay persons alike the order of magnitude of the potential improvement in prognosis for breast cancers detected while yet asymptomatic, were worthy objectives of this educational venture.

Summary

To help acquaint physicians and lay persons with both the methods and the importance of the early detection of breast cancer, five breast cancer education-examination clinics and seminars have been held since 1961. A total of 5,438 women were examined. About 6% of the women seen at the clinics were re-evaluated by their local physicians upon the recommendation of the clinic examiners. More than half of the patients who returned to their private doctors were found on re-examination to have definite breast abnormalities, and about 44% of those with "confirmed" abnormalities underwent breast biopsies. The lesion most commonly detected was fibrocystic disease, which was found in 25 of each 1,000 women seen in the clinics and accounted for 77% of the "confirmed" breast abnormalities. Eight breast cancers were detected (1.5 cancers per 1,000 women examined).

The ease and simplicity as well as the importance of breast examinations in asymptomatic persons were demonstrated to thousands of women and to hundreds of physicians and nurses in the several areas in the state.

In Fractures: B and C vitamins are therapy

Stress formula vitamins are a key factor in bone and tissue regeneration. To meet the increased metabolic demands, STRESSCAPS offers therapeutic amounts of B and C vitamins as an aid to smoother convalescence and earlier rehabilitation. In fractures, as in many other conditions of physiologic stress, STRESSCAPS vitamins are therapy.

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

History of Medicine

The Discovery of Insulin

The first description of diabetes dates back to about 1500 B.C., as presented in the Papyrus Ebers, wherein the symptoms of the disease, which we now call diabetes were described. These symptoms were later described in greater detail by the encyclopedist Celsus at the time of Julius Caesar.

In 1869 an anatomist, Dr. Paul Langerhans, though not realizing any relationship between the pancreas and diabetes, gave us an anatomical description of the pancreatic tissue by noting certain microscopic nests of cells imbedded therein, which are now known as the Islets of Langerhans.

The true nature of the relationship of the pancreas to diabetes was not identified until 1889, when von Mering and Minkowski demonstrated that the removal of the pancreas in dogs resulted in diabetes, although this still did not clarify which of the two types of tissue in the pancreas was responsible for controlling the sugar metabolism.

Little progress was made in the understanding of the relation of the pancreas to diabetes until 1900, when Dr. E. L. Opie of Johns Hopkins University described the presence of pathological changes in the Islets found in cases of diabetes studied at postmortem. Many preceding observers had speculated that a hormone was probably secreted internally by the Islets and carried directly by the blood stream, thus controlling the metabolism of sugar. Attempts had been made to treat diabetics by feeding pancreatic tissue or its extract to the patients, or by injecting the extract. But no satisfactory clinical results were obtained.

It was not until 1922 that any successful treatment for diabetes was finally achieved. A young orthopedic surgeon from New London, Ontario, Dr. Fredrick G. Banting, quite by accident came upon the clue which led him to the discovery of insulin.

In his speech delivered at the dedication ceremony of the new Eli Lilly Research Laboratories in Indianapolis in 1934, Sir Frederick Banting (he had since been knighted for his discovery) tells how this discovery came about. He relates how, after struggling in the practice of orthopedic surgery for several months without success in making a livelihood, he decided to take a part-time position as demonstrator in the department of physiology and anatomy at the University of London, Ontario.

On October 30, 1920, when he was preparing a lecture on the relation of the pancreas to diabetes, there came to his attention an article on the pancreas in the newly-arrived November issue of "Surgery, Gynecology, and Obstetrics." To quote Dr. Banting: "This journal contained an article by Moses Barron, in which he pointed out the analogy between the degenerative changes which followed experimental ligation of the pancreatic duct and that of the blockage of the duct by pancreatic stones.

"After reading the article by Barron, I was unable to sleep." Dr. Banting tells at this point how he jotted down in his notebook: "Ligate pancreatic ducts of dogs, wait six to eight weeks for degeneration, remove the residue and extract."

The next morning he consulted a colleague, on whose advice he went to the University of Toronto, his alma mater, to consult Professor J. J. R.

Continued

Macleod, head of the department of physiology and an authority on carbohydrate metabolism, to obtain facilities necessary to carry out the research he contemplated.

But he got little encouragement from Professor Macleod, who asked him what "he hoped to accomplish, when the best-trained physiologists had not succeeded in establishing or proving that there was an internal secretion of the pancreas." As consultations with other colleagues were equally discouraging, it was decided that Dr. Banting go back to his medical practice and teaching in London, Ontario, to complete the term. After four months he returned to Toronto and asked Macleod to be allowed to tie the pancreatic ducts of a number of dogs.

On May 16, 1921, Banting began his experiments. He was allowed the services of two graduate students, Mr. Best and Mr. Noble, each to give assistance for a period of four weeks. In the talk he gave at Indianapolis, Dr. Banting relates an interesting incident which shows what a significant role fate can sometimes play. Mr. Best and Mr. Noble "tossed a coin to decide who would give the first four weeks, and Mr. Best won the toss. At the end of the four weeks Mr. Noble could not return, and Mr. Best stayed with me and was associated with me throughout the entire work."

The experiments which Dr. Banting and his associates carried on consisted of ligating the pancreatic ducts of the dogs, waiting six weeks for the degeneration and atrophy of the secretory glands which produce the digestive ferments, and watching for the degeneration of the enzymatic secretory glands. The result hoped for was that all this would take place, leaving the Islets of Langerhans intact. And this did actually happen. The experiment of injecting the extract of the degenerated pancreatic tissue had proved a success.

Extracts were then made of the degenerated pancreatic tissue, and after injecting the extract into normal and diabetic dogs, it was found that the blood sugar had actually been lowered.

On January 11, 1922, the extract was first used on patients in the Toronto General Hospital. The treatment of the patients was equally successful. At this point Dr. Macleod, becoming enthusiastic about the results, turned over most of his laboratory staff to the problem.

The task of chemical refinement was assigned to Dr. J. G. Collip, who quickly succeeded in producing a less toxic and more active product. It was later in the spring of 1922 that Dr. Best, because of his experience in chemistry, was able to make possible the production of insulin in larger quantities and still higher purity. However, the product continued to produce sensitization reactions, and it was not before January 1923 that, through the collaboration of the laboratories of Connaught and of Eli Lilly and Company on the production of insulin, the product became stable and pure.

The problem of quantity of insulin production fortunately was solved through chemical experimentation through which it was found that acidified alcohol dissolved the antidiabetic hormone produced by the Islets of Langerhans *without* dissolving the enzymatic secretions of the pancreas.

[*] Professor Emeritus, Medical School, University of Minnesota.

Excerpts from a Presidents Address*

Ladies and gentlemen of the Minnesota State Medical Society,

I thank you most heartily for the honor you have conferred upon me, and in the discharge of my duties as your presiding officer I will endeavor to act impartially. As a profession it is well for us to stop our scientific labors occasionally and, looking about, see if we have fulfilled our trust to the public and maintained our high position as the most progressive and enlightened of the learned professions.

Let us have the patience of a righteous cause and await this slow but sure progress. It is humiliating to members of our profession to see so many positions of public trust held by irregulars — but we must recollect that the world is not run by the highest thought but by the average intelligence, and the right of the minority to representation is but justice.

Our relations with *the clerical profession* as a whole are satisfactory. There are certain inherent differences between the professions which render a common point of view somewhat difficult. Our profession is nothing if not progressive, and medical history is useful only so far as having led up to the present and as a basis for the future. The theological profession is based upon the past and is history repeating itself with such modifications as have been forced upon it from the outside. They guard a secret trust and view innovation with alarm. The eager striving of the medical profession for the new gives to them an apparently materialistic tendency, while the faith of the clergy is only too often exaggerated into gullibility, and leads them to the recommendation of various patent remedies for the cure of incurable disease, and the endorsement of secret compounds to which they too frequently lend their name and influence. Let us charitably look upon this as merely an evidence of atavism from our common ancestor, the priest physician of the middle ages. These fraternal differences, it is to be hoped, will only cement more closely the hereditary ties and, in the future as in the past, the two professions will go hand in hand.

With *the legal profession* we work in the most perfect harmony outside the courtroom, but as medical witnesses we are an exhibition — a sight for gods and men. The physician is an egotist of necessity. He must give his patients confidence in order to secure that tranquility of mind so necessary for their welfare. — The opinion of a medical witness is based frequently upon technical evidence which cannot be explained to those not educated to his line of thought, and with the hypothetical question the changing of a single word will give grounds for medical experts to honestly differ.

Our relations with *the press* are peculiar but not inharmonious. — As a profession I think sometimes we are a little bit inclined to claim immunity from the common errors and to play something of the oracle. The press hears much about our code of ethics but finds, if our names are found in the paper in the account of an accident or at the bottom of a daily bulletin of our illustrious patients, that our feelings are not so deeply lacerated after all. We must explain to our friends of the pencil that we are human, but that our profession is divine.

We will admit many personal shortcomings but insist that *our code of ethics* is not the superannuated farce they believe it to be, but that it contains the opinion of the profes-

*W. J. Mayo, M.D., Transactions of Minnesota State Medical Society, 1894. Obtained through courtesy of Charles G. Sheppard, M.D., Le Sueur, Minn., who's father practiced in Minnesota for more than fifty years.

sion as to how gentlemen should act who hold confidential relations with their patients. This leads me to the prominent question before the American Medical Association: shall we have a change in our code of ethics, leave it alone, or wipe it out utterly. — I see no good reason why we should meddle with it. It simply explains how a gentleman acts while engaged in the practice of medicine.

Pertaining to *personal damage suits* for malpractice — the physician in the course of his whole duty is often exposed to ill timed and often unjust criticism; to attempt to secure special protection from this annoyance is to demand class legislation which would in the long run damage us in public opinion more than we would gain. I believe on the whole that we had best leave this matter to the common justice of the people.

It is a matter of state pride to us to note that in the discussion of some form of public control, our societies have promptly placed themselves in line with the most advanced thought.

Our transactions have been very well presented by the Northwestern Lancet during the past year and our state is to be congratulated upon having so excellent an organ in its midst, and its editors and publishers should be thanked by this society for the literary and artistic merit of its publication; not only in medical literature but in medical education are we to be felicitated.

Our great University medical department from small beginnings has rapidly advanced to a proud position of eminence for which our profession may be justly proud. —

In conclusion I would call your attention to the most excellent scientific program which in itself is an indication of progress and industry of our fellows.

Editor's Note: Doctors! We are still being watched!

Gulliver's Travels — Jonathan Swift

Gulliver — On How to Sue a Neighbor for his Cow

"If my neighbor hath a mind to my cow, he hires a lawyer to prove that he ought to have my cow from me. I must then hire another to defend my right; it being against all rules of law that any man should be allowed to speak for himself. — I, who am the true owner, lie under two great disadvantages. First, my lawyer being practiced almost from his cradle in defending falsehood, is quite out of his element when he would be an advocate for justice —. The second disadvantage is, that my lawyer must proceed with great caution: or else he will be reprimanded by the judges, and abhorred by his brethren, as one who would lessen the practice of the law. And therefore I have but two methods to preserve my cow. The first is, to gain over my adversary's lawyer with a double fee; who will then betray his client, by insinuating that he has justice on his side. The second way is for my lawyer to make my cause appear as unjust as he can; by allowing the cow to belong to my adversary; and if it be skilfully done, will certainly bespeak the favor of the bench.

They never desire to know what claim or title my adversary has to my cow; but whether the said cow were red or black; her horns long or short; whether the field I graze her in be round or square; whether she were milked at home or abroad; what diseases she is subject to, and the like. After which they consult precedents, adjourn the cause from time to time, and in ten, twenty, or thirty years come to an issue."

(To be continued.)

113th Annual Meeting

St. Paul Awaits Minnesota Physicians in 1966

Computer Medicine: Its Application Today and Tomorrow, a subject with an increasing amount of interest among physicians and lay persons alike, will be among the topics presented at the scientific sessions of the 113th Annual Meeting of the Minnesota State Medical Association, May 16 and 17 in St. Paul.

The scientific sessions will be held in the St. Paul Municipal Auditorium and the House of Delegates will convene in the St. Paul Hotel.

The opening scientific session devoted to Computer Medicine, scheduled to begin Monday, May 16, at 9:00 A.M., will feature a presentation by Morris F. Collen, Oakland, California. Doctor Collen is a former Minnesotan, now with the Permanente Medical Group in California. His presentation will be based upon his vast experience using computers extensively in physical examinations and diagnostic tests.

Other general scientific sessions on this year's annual meeting program will be on the subjects of hematology; obstructive respiratory diseases; treatment of burns; respiratory distress syndrome in the newborn; isotopes; hyperthyroidism; prevention of knee injuries; juvenile diabetes; treatment of staph and strep infections and the early recognition and treatment of blindness.

The program on Monday and Tuesday is acceptable for 4½ credit hours by the American Academy of General Practice. In addition, there will be an opportunity for physicians to attend the traditionally popular noon Round Table luncheons Monday and Tuesday at the St. Paul Hotel. The opening round of luncheons will be on the subjects of Fluids in Infancy; The Spiritual Dimension of Suffering; The Use of Saline Solutions in the Treatment of Hemorrhagic and Traumatic Shock; Treatment of Leukemia; Management of

Continued

Emphysema; and Computers in Preventive Medical Research.

Tuesday round table topics are as follows: Prevention and Treatment of Ankle Injuries; Value and Use of the Tonometer; The Brittle Diabetic; Radioactive Isotopes in Clinical Practice; Amniocentesis, A Diagnostic and Therapeutic Tool; and Therapeutic Abortion in General and in Rubella.

Noting the increased interest in Medicine and Religion and the enthusiastic response to this important subject shown at last year's meeting, the Committee on Scientific Assembly is pleased to announce that a panel on "The Dying and the Dead" has been scheduled for Monday at 2:30 P.M. Panelists will include: Harold W. Hermann, M.D., Minneapolis, as moderator; Bishop James P. Shannon, St. Paul; Reverend Elmer Hjortland, Oak Park, Illinois; and Rabbi Albert G. Minda, Minneapolis.

Organizations and specialty groups planning events in conjunction with this meeting include the Minnesota Radiological Society, Minnesota Chapter of the American Academy of Pediatrics, Twin Cities Diabetes Association, Minnesota Chapter, American College of Chest Physicians, Minnesota Academy of Ophthalmology and Otolaryngology and The Medical Women's Association. The Minnesota Academy of General Practice will hold its Annual Banquet Monday evening. The Annual Banquet of the Minnesota State Medical Association will be held Tuesday evening. The new members, officers and delegates dinner at 6:00 P.M. will follow the opening session of the House of Delegates Sunday, May 15. The House of Delegates will convene Sunday, May 15, at 2:00 P.M. and again Tuesday, May 17, at 9:00 A.M.

The concluding scientific session on Tuesday at 4:00 P.M. will feature an obstetrics and gynecology seminar. Seminar topics scheduled are: Endometriosis, the Conservative vs. the Radical Surgical Treatment; and Early Invasive Carcinoma of the Cervix.

An impressive selection of scientific and technical exhibits will be on display Monday and Tuesday at the St. Paul Auditorium. Physicians are invited to visit the exhibits and to express their appreciation to the technical exhibitors whose participation annually helps to make this meeting possible.

The official program including detailed information about scientific, business and social activities will be mailed to all members. Kindly check the official Annual Meeting program for complete details.

Scientific Program
Saint Paul Auditorium

MONDAY MORNING, MAY 16, 1966

The program on Monday is acceptable for 4½ accredited hours by the American Academy of General Practice.

A.M. Visit scientific and technical exhibits

9:00 **COMPUTER MEDICINE: ITS APPLICATION TODAY AND TOMORROW**
Morris F. Collen, Oakland, California

9:40 **WHAT'S NEW IN HEMATOLOGY?**
A. B. Hagedorn, Rochester

Program Highlights

. . . Dr. James Z. Appel, President of the American Medical Association, will address the House of Delegates at their opening session on Sunday, May 15. He will also be the speaker at the New Members, County Officers and Delegates dinner on Sunday evening.

. . . Please reserve Wednesday, May 18, following the annual meeting for an all-day session on the latest developments in Medicine. Mr. Roy K. Marquardt, regional representative for Health Insurance, Department of Health, Education and Welfare, is being asked to report on the up-to-the-minute status of Medicare. Other officials directly concerned with the program will also participate.

. . . For golfers — The annual golf tournament will be held on Sunday, May 15, at the White Bear Yacht Club followed by a dinner at 7:00 p.m. to which all members of the Association and their wives are cordially invited.

. . . Special attention is called to the day-long session on Monday of the Minnesota Society of Clinical Pathologists which begins at 9:00 a.m. at the Minnesota Club and continues through 4:30 p.m. The program will include a symposium on "Evaluation of Thyroid Function," and beginning at 2:00 p.m. "Case Reports" with panelists.

. . . Advance registration card for the meeting and the card for hotel accommodations were sent to all members with the Association's March newsletter. Use of these cards will save you time and greatly facilitate your attendance at the meeting.

. . . All high school coaches in the Twin Cities and surrounding area have been invited to hear Dr. Harvey O'Phelan and Professor Lloyd Stein discuss "Prevention and Treatment of Knee Injuries in the Athlete," a highlight of the Tuesday morning scientific session.

. . . The Association's 4th duplicate bridge tournament will begin at 9:00 p.m. on Monday night at the Saint Paul Hotel. It is open to all bridge players, duplicate experience is not necessary.

Sustained circulatory, respirator
and cerebral stimulation for th

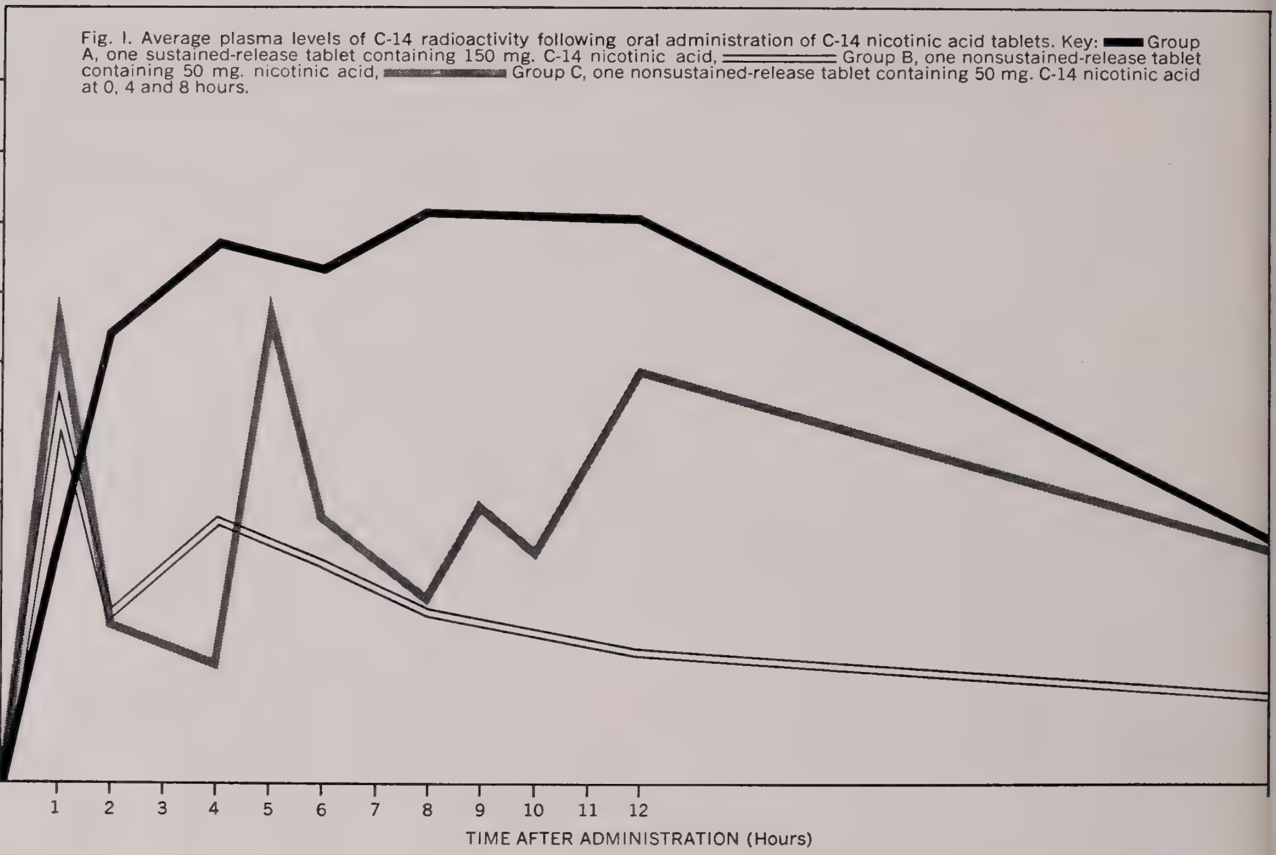

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ■ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▨ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

ged and debilitated

TIME AFTER ADMINISTRATION (Hours)

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

In Memoriam

The darkness of death is like the evening twilight; it makes all objects appear more lovely to the dying. — Richter.

HAROLD F. WAHLQUIST, M.D.

Dr. Harold F. Wahlquist, 72, Minneapolis physician, died February 5. He was a former chief of the medical staff at Methodist Hospital and charter member of the mayor's mental health board to organize a children's psychiatric clinic at General Hospital in 1958. He also was a former delegate to the World Health Organization and member of the Board of Directors of the Minneapolis Society for the Blind, Inc.

Dr. Wahlquist was born in Duluth, Minnesota and received his doctor's degree from the University of Minnesota Medical School. He was a member of the Hennepin County Medical Society, Minnesota State Medical Association and American Medical Association.

He is survived by his son and two daughters.

ALFRED L. LINDBERG, M.D.

Dr. A. L. Lindberg, 71, Wheaton physician, died February 10th in a Breckenridge hospital after a short illness. He was born in St. Peter, and upon earning his B.S. degree, taught in Long Prairie for a few years. This career was interrupted by his enlistment in the U. S. Army where he was inducted into the medical corps. Here he became interested in medicine and decided to enter the profession. He received his medical degree at the College of Medicine, University of Minnesota, in 1922, and after interning in Duluth, went to Wheaton in 1924. Dr. Lindberg practiced in Wheaton until 1961 when he retired from active practice.

He was a member of the West Central Minnesota Medical Society, Minnesota State Medical Association and the American Medical Association. His death came shortly before plans were completed by the people of Wheaton for a community-wide recognition program in his honor to be held in April.

He is survived by his wife.

OLIVER E. SARFF, M.D.

Dr. Oliver E. Sarff, 65, Duluth physician and urologist for many years, died January 16, following a long illness. Born in Milbank, South Dakota, he graduated from the University of Minnesota Medical School.

From 1961 to 1963 Dr. Sarff was surveyor for the Joint Commission of Accreditation of Hospitals. He was a member of the St. Louis County Medical Society, the American Medical Association, American College of Surgeons, American Board of Urology, American Urological Association and an associate member of the Minnesota State Medical Association.

He is survived by his son, Dr. Allen Sarff of Duluth, and a daughter.

MERRILL A. HOWARD, M.D.

Dr. Merrill A. Howard, 69, St. Paul physician, died March 1 in his home. He was born in Wells, Minnesota, and had lived in St. Paul for forty-four years.

Dr. Howard retired eight years ago from the practice of medicine because of ill health. He was a member of the American Legion Post 447, Ludwig Lodge 311, the American Medical Association, the Academy of General Practice, the Ramsey County Medical Society and an associate member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

EDWARD E. NOVAK, M.D.

Dr. Edward E. Novak, 92, a New Prague physician for seventy years and a well-known educator and livestock breeder, died March 7th. Born in Iowa, he received his medical degree from the University of Iowa in 1895. He began practice in New Prague the same year.

He was a University of Minnesota regent from 1937 to 1955 and was a former president of the Minnesota School Board Association. He had been a member of the New Prague School Board for forty years. Dr. Novak was a member of the Scott-Carver County Medical Society the American Medical Association. He was a life and 50 Club member of the Minnesota State Medical Association.

He is survived by his son and a daughter.
